

# MIPI D-PHY v4.3

## *LogiCORE IP Product Guide*

Vivado Design Suite

PG202 (v4.3) December 4, 2024

AMD Adaptive Computing is creating an environment where employees, customers, and partners feel welcome and included. To that end, we're removing non-inclusive language from our products and related collateral. We've launched an internal initiative to remove language that could exclude people or reinforce historical biases, including terms embedded in our software and IPs. You may still find examples of non-inclusive language in our older products as we work to make these changes and align with evolving industry standards. Follow this [link](#) for more information.

# Introduction

The AMD MIPI D-PHY Controller is designed for transmission and reception of video or pixel data for camera and display interfaces. The core is used as the physical layer for higher level protocols such as the Mobile Industry Processor Interface (MIPI) Camera Serial Interface (CSI-2) and Display Serial Interface (DSI).

This product guide provides information about using, customizing, and simulating the core for AMD UltraScale+™ and 7 series FPGA families as well as AMD Versal™ Adaptive SoCs. It also describes the core architecture and provides details on customizing and interfacing to the core.

---

## Features

- Compliant to [MIPI Alliance Standard for D-PHY Specification](#), version 2.0.
- Synchronous transfer at high-speed mode with a bit rate of 80-3200 Mb/s depending on the device family and speed grade. For details about line rate support, refer to the respective data sheets.
- One clock lane and up to four data lanes for TX configuration.
- One clock lane and up to eight data lanes for RX configuration.
- Asynchronous transfer at low-power mode with a bit rate of 10 Mb/s.
- Ultra low-power mode, and high-speed mode for clock lane.
- Ultra low-power mode, high-speed mode, and escape mode for data lane.
- PHY-Protocol Interface (PPI) to connect CSI-2 and DSI applications.
- Optional AXI4-Lite interface for register access.

# IP Facts

**Notes:**

1. For a complete list of supported devices, see the AMD Vivado™ IP catalog.
2. For the supported versions of the tools, see the *Vivado Design Suite User Guide: Release Notes, Installation, and Licensing* ([UG973](#)).

# Overview

The MIPI D-PHY Controller is a full-featured IP core, incorporating all the necessary logic to properly communicate on this high-speed I/O interface standard. The core supports transmission/reception of camera sensor and video data from/to a standard-format PHY-Protocol Interface (PPI) using the high-speed SelectIO™ interface.

The following figure shows a high-level view of the MIPI D-PHY with all its components:

*Figure 1: D-PHY IP Overview*

X23420-102319

## Navigating Content by Design Process

AMD Adaptive Computing documentation is organized around a set of standard design processes to help you find relevant content for your current development task. You can access the AMD Versal™ adaptive SoC design processes on the [Design Hubs](#) page. You can also use the [Design Flow Assistant](#) to better understand the design flows and find content that is specific to your intended design needs. This document covers the following design processes:

- **Hardware, IP, and Platform Development:** Creating the PL IP blocks for the hardware platform, creating PL kernels, functional simulation, and evaluating the AMD Vivado™ timing, resource use, and power closure. Also involves developing the hardware platform for system integration. Topics in this document that apply to this design process include:
  - [Port Descriptions](#)
  - [Register Space](#)
  - [Clocking](#)
  - [Resets](#)
  - [Customizing and Generating the Core](#)
  - [Chapter 6: Example Design](#)

---

## Feature Summary

The MIPI D-PHY Controller can be configured as a Master (TX) or Slave (RX). It supports high-speed data transfer up to 3200 Mbps, and control data can be transferred using Low-Power Data Transfer mode at 10 Mb/s. The PPI interface allows a seamless interface to DSI and/or CSI IP cores. Using the MIPI D-PHY core AMD Vivado™ Integrated Design Environment (IDE)-based I/O planner, you can customize the data lane(s) selection by selecting the I/O bank followed by the clock lane. Optionally, the MIPI D-PHY core provides an AXI4-Lite interface to update the protocol timer values and retrieve the core status for debugging purposes.

---

## Applications

The MIPI D-PHY Controller can be used to interface with the MIPI CSI-2 and DSI controller TX/RX devices. This core allows for seamless integration with higher level protocol layers through the PPI.

---

## Unsupported Features

The following features of the standard are not supported in the MIPI D-PHY Controller:

- Link turnaround (reverse data communication)
- Low-power contention detection
- 8B9B encoding

- Dynamic line rate change

---

## Licensing and Ordering

This AMD LogiCORE™ IP module is provided at no additional cost with the AMD Vivado™ Design Suite under the terms of the [End User License](#).

**Note:** To verify that you need a license, check the License column of the IP catalog. Included means that a license is included with the AMD Vivado™ Design Suite; Purchase means that you have to purchase a license to use the core.

Information about other AMD LogiCORE™ IP modules is available at the [Intellectual Property](#) page. For information about pricing and availability of other AMD LogiCORE IP modules and tools, contact your [local sales representative](#).

# Product Specification

The MIPI D-PHY Controller is a physical layer that supports the MIPI CSI-2 and DSI protocols. It is a universal PHY that can be configured as either a transmitter or a receiver. The core consists of an analog front end to generate and receive the electrical level signals, and a digital backend to control the I/O functions.

The MIPI D-PHY Controller provides a point-to-point connection between master and slave, or host and device that comply with a relevant MIPI standard. A typical TX configuration consists of 1 clock lane and 1 to 4 data lanes and a typical RX configuration consists of 1 clock lane and 1 to 8 data lanes. The master/host is primarily the source of data, and the slave/device is usually the sink of data. The D-PHY lanes can be configured for unidirectional lane operation, originating at the master and terminating at the slave. The core can be configured to operate as a master or as a slave. The D-PHY link supports a high-speed (HS) mode for fast data traffic and a low-power (LP) mode for control transactions:

- In HS mode, the low-swing differential signal supports data transfers from 80 Mb/s to 3200 Mb/s.
- In LP mode, all wires operate as a single-ended line capable of supporting 10 Mb/s asynchronous data communications.

---

## Standards

This core is designed to be compatible with the [MIPI Alliance D-PHY Specification](#). For a list of supported devices, see the AMD Vivado™ IP catalog.

---

## MIPI D-PHY TX (Master) Core Architecture

The following figure shows the MIPI D-PHY TX (Master) core architecture for AMD UltraScale+™ families and AMD Zynq™ UltraScale+™ MPSoC devices. The TX core is partitioned into three major blocks:

- **TX Physical Coding Sublayer (PCS) Logic:** Provides the PPI to the core and generates the necessary controls to the PHY for the lane operation. It also generates entry sequences, line switching between low power and high speed, and performs lane initialization.

- **TX PHY Logic:** Integrates the BITSlice\_CONTROL and TX\_BITSLICE in native mode and D-PHY-compatible I/O block. This block does serialization and has clocking implementation for the PHY.
- **Register Interface:** Optional AXI4-Lite register interface to control mandatory protocol timers and registers.

Figure 3: MIPI D-PHY TX (Master) Core Architecture for UltraScale+ Families

X17792-090116

The following figure shows the MIPI D-PHY TX (Master) Core Architecture for Versal Adaptive SoC.

Figure 5: MIPI D-PHY TX (Master) Core Architecture for Versal Adaptive SoC

X24901-120920

## MIPI D-PHY RX (Slave) Core Architecture

The following figure shows the MIPI D-PHY RX (Slave) core architecture for AMD UltraScale+™ families and AMD Zynq™ UltraScale+™ MPSoC devices. The RX core is partitioned into three major blocks:

- **RX PCS Logic:** Interfaces with PHY and delivers PHY-Protocol Interface (PPI)-compliant transactions such as High-Speed and Escape mode Low-Power Data Transmission (LPDT) packets. It is also responsible for lane initialization, start-of-transmission (SoT) detection, and clock recovery in escape mode.
- **RX PHY Logic:** Performs clock recovery in high-speed mode and de-serialization. Integrates the BITSlice\_CONTROL and RX\_BITSlice in native mode and D-PHY compatible I/O block.

- **Register Interface:** Optional AXI4-Lite register interface to control protocol mandatory timers and registers.

Figure 6: MIPI D-PHY RX (Slave) Core Architecture for UltraScale+ Families

The following figure shows the MIPI D-PHY RX (Slave) Core Architecture for the 7 series FPGA families.

Figure 7: MIPI D-PHY RX (Slave) Core Architecture for 7 Series FPGA Families

X26344-022522

The following figure shows the architecture for MIPI D-PHY RX (Slave) Core Architecture for Versal device families

**D-PHY RX IP**

The diagram illustrates the internal structure of the D-PHY RX IP, which is divided into three main functional blocks:

- RX Fabric Logic (PCS):** This block contains the core processing logic for multiple lanes.
  - Clock Lane:** Includes Timers, HS\_CLK\_RCVR, ULPS\_BLK, and PHY\_CTRL.
  - Data Lane0:** Includes Timers, HS\_BLK, ESC\_DEC, and PHY\_CTRL.
  - Data Lane7:** Includes Timers, HS\_BLK, ESC\_DEC, and PHY\_CTRL.
- RX PHY Logic:** This block contains the physical layer logic.
  - XPHY:** Receives data from the PCS and outputs to the NIBBLE SLICE.
  - NIBBLE SLICE:** Processes the data from XPHY and outputs to the IOB.
  - IOB:** Receives data from the NIBBLE SLICE and outputs to the IBUFDS\_D PHY.
  - IBUFDS\_D PHY:** Receives data from the IOB and outputs to the external Data Lane.
- Register Interface:** Connected to the PCS via an AXI4-LITE IF, it provides a control interface for the IP.

**External Interfaces and Connections:**

- RX PPI:** Connected to the PCS via a bidirectional interface.
- Clock Lane:** Connected to the external Clock Lane via a bidirectional interface.
- Data Lane 0:** Connected to the external Data Lane 0 via a bidirectional interface.
- Data Lane 7:** Connected to the external Data Lane 7 via a bidirectional interface.

**Data Flow and Signaling:**

- The data flow from the PCS to the PHY Logic is indicated by arrows with labels: 2/ (from PCS to PHY Logic), 8/ (from PHY Logic to PCS), and 2/ (from PHY Logic to PCS).
- The data flow from the PHY Logic to the external Data Lane is indicated by arrows with labels: 2/ (from PHY Logic to Data Lane) and 8/ (from Data Lane to PHY Logic).

Enabling this mode allows the received PPI RX input data to be sent as MIP TX Data duplicated on multiple DPHY TX Interfaces. You can select up to a maximum of four TX Interfaces as shown in the following figure. GUI allows to SelectIOfor each interface. You need to ensure that the IOs are exclusive across interfaces. The IOs of each interface can be same or different banks.

Figure 9: MIPI D-PHY – D-PHY Splitter Bridge

This mode is best suited for cases where same camera data needs to be processed by multiple external processing modules. In such cases, the AMD FPGA receives the MIPI stream from the external source (camera) and replicates on multiple output MIPI stream interfaces for further processing by external modules.

Figure 10: D-PHY Splitter Bridge Use Case

## Performance and Resource Use

For full details about performance and resource use, visit the [Performance and Resource Use web page](#).

## Maximum Frequencies

The maximum frequency of the core operation is dependent on the supported line rates and the speed grade of the devices.

## Latency

The MIPI D-PHY TX core latency is measured from the `requesths` signal of the data lane assertion to the `readyhs` signal assertion.

The MIPI D-PHY RX core latency is the time from the start-of-transmission (SoT) pattern on the serial lines to the `activehs` signal assertion on the PPI. The following table provides the latency numbers for various core configurations.

**Note:** To calculate the throughput for higher lanes, multiply the existing throughput by the configured number of lanes.

**Table 1: Latency for D-PHY Core Configurations**

| Line Rate (Mb/s) | LPX (ns) | Device Family       | Lanes | Latency (in byteclkhs <sup>1</sup> cycles) | Data Flow Mode    |
|------------------|----------|---------------------|-------|--------------------------------------------|-------------------|
| 250              | 50       | UltraScale+         | 1     | 10                                         | D-PHY TX (Master) |
| 500              | 50       | UltraScale+         | 1     | 18                                         | D-PHY TX (Master) |
| 1,000            | 50       | UltraScale+         | 1     | 33                                         | D-PHY TX (Master) |
| 1,250            | 50       | UltraScale+         | 1     | 43                                         | D-PHY TX (Master) |
| 1,500            | 50       | UltraScale+         | 1     | 51                                         | D-PHY TX (Master) |
| 2,000            | 50       | UltraScale+         | 1     | 67                                         | D-PHY TX (Master) |
| 2,500            | 50       | UltraScale+         | 1     | 84                                         | D-PHY TX (Master) |
| 3200             | 50       | Versal Adaptive SoC | 1     | 194                                        | D-PHY TX (Master) |
| 250              | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 500              | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 1,000            | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 1,250            | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 1,500            | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 2,000            | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 2,500            | 50       | UltraScale+         | 1     | 6                                          | D-PHY RX (Slave)  |
| 3200             | 50       | Versal Adaptive SoC | 1     | 6                                          | D-PHY RX (Slave)  |
| 250              | 50       | 7 series            | 1     | 16                                         | D-PHY TX (Master) |
| 500              | 50       | 7 series            | 1     | 24                                         | D-PHY TX (Master) |
| 1,000            | 50       | 7 series            | 1     | 39                                         | D-PHY TX (Master) |
| 1,250            | 50       | 7 series            | 1     | 48                                         | D-PHY TX (Master) |
| 250              | 50       | 7 series            | 1     | 5                                          | D-PHY RX (Slave)  |
| 500              | 50       | 7 series            | 1     | 5                                          | D-PHY RX (Slave)  |
| 1,000            | 50       | 7 series            | 1     | 5                                          | D-PHY RX (Slave)  |

Table 1: Latency for D-PHY Core Configurations (cont'd)

| Line Rate (Mb/s) | LPX (ns) | Device Family | Lanes | Latency (in byteclkhs <sup>1</sup> cycles) | Data Flow Mode   |
|------------------|----------|---------------|-------|--------------------------------------------|------------------|
| 1,250            | 50       | 7 series      | 1     | 5                                          | D-PHY RX (Slave) |

**Notes:**

1. Frequency of byteclkhs (MHz) = line rate in Mb/s divided by 8.
2. Latency is dependent on line rate, LPX period, HSPREPARE time, and HSZERO time.

## Throughput

The MIPI D-PHY TX core throughput varies based on line rate, number of data lanes, clock lane mode (continuous or non-continuous) and D-PHY protocol parameters. Throughput is measured from the clock lane `txrequesths` signal assertion to the clock lane `txrequesths` signal deassertion by transferring a standard 640x480 resolution image as frame data on the PPI. In this measurement, the number of bytes transferred from the start to the end are taken into account. Data lane `txrequesths` and `txreadyhs` assertion is considered as one-byte transfer. The following table provides the throughput numbers for various core configurations.

Table 2: Throughput for MIPI D-PHY TX Core Configurations

| Line Rate (Mb/s) | LPX (ns) | Device Family            | Lanes | Throughput (Mb/s) | Data Flow Mode    |
|------------------|----------|--------------------------|-------|-------------------|-------------------|
| 250              | 50       | UltraScale+              | 1     | 239               | D-PHY TX (Master) |
| 500              | 50       | UltraScale+              | 1     | 462               | D-PHY TX (Master) |
| 1,000            | 50       | UltraScale+              | 1     | 879               | D-PHY TX (Master) |
| 1,250            | 50       | UltraScale+              | 1     | 1075              | D-PHY TX (Master) |
| 1,500            | 50       | UltraScale+              | 1     | 1261              | D-PHY TX (Master) |
| 2000             | 50       | UltraScale+              | 1     | 1661              | D-PHY TX (Master) |
| 2500             | 50       | UltraScale+              | 1     | 2002              | D-PHY TX (Master) |
| 2936             | 50       | AMD Versal™ Adaptive SoC | 1     | 2212              | D-PHY TX (Master) |
| 3200             | 50       | AMD Versal™ Adaptive SoC | 1     | 2385              | D-PHY TX (Master) |
| 250              | 50       | 7 series                 | 1     | 231               | D-PHY TX (Master) |
| 500              | 50       | 7 series                 | 1     | 462               | D-PHY TX (Master) |
| 1,000            | 50       | 7 series                 | 1     | 879               | D-PHY TX (Master) |
| 1,250            | 50       | 7 series                 | 1     | 1066              | D-PHY TX (Master) |

## Port Descriptions

The external interface of the core is PPI, and the AXI4-Lite interface is optionally available for register programming.

## PPI Signals

The MIPI D-PHY core provides PPI signaling for clock lane and data lane operation. The signal ports are listed in the following tables. In these tables <n> is the configurable data lane number (0 to 3).

**Table 3: Common PPI Control Signals**

| Signal                                | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cl_stopstate, dl<n>_stopstate         | Output    | Async        | Lane is in Stop state.<br>This active-High signal indicates that the Lane module (TX or RX) is currently in the Stop state. Also, the protocol can use this signal to indirectly determine if the PHY line levels are in the LP-11 state.<br><b>Note:</b> This signal is asynchronous to any clock in the PPI.                                                                                                                                                                                                                                |
| cl_enable, dl<n>_enable               | Input     | Async        | Enable Lane Module.<br>This active-High signal forces the lane module out of "shutdown". All line drivers, receivers, terminators, and contention detectors are turned off when Enable is Low. When Enable is Low, all other PPI inputs are ignored and all PPI outputs are driven to the default inactive state. Enable is level sensitive and does not depend on any clock.                                                                                                                                                                 |
| cl_ulpsactivenot, dl<n>_ulpsactivenot | Output    | Async        | ULP State (not) Active.<br>This active-Low signal is asserted to indicate that the Lane is in the ULP state. For a receiver, this signal indicates that the Lane is in the Ultra Low Power (ULP) state. At the beginning of the ULP state, ulpsactivenot is asserted together with rxulpsesc, or rxclkulpsnot for a clock lane. At the end of the ULP state, this signal becomes inactive to indicate that the Mark-1 state has been observed. Later, after a period of time (Twakeup), the rxulpsesc (or rxclkulpsnot) signal is deasserted. |

**Table 4: D-PHY TX Clock Lane High-Speed PPI Signal**

| Signal           | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                    |
|------------------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cl_txrequesths   | Input     | txbyteclkhs  | High-Speed Transmit Request and Data Valid.<br>For clock lanes, this active-High signal causes the lane module to begin transmitting a high-speed clock.<br><b>Note:</b> cl_requesths should only be asserted after the init_done is High, until then it should be driven as 0 |
| cl_txclkactivehs | Output    | txbyteclkhs  | This active-High signal indicates that the clock is being transmitted on the clock lane.                                                                                                                                                                                       |

Table 5: D-PHY TX Clock Lane Escape Mode PPI Signals

| Signal        | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| cl_txulpsclk  | Input     | core_clk     | Transmit Ultra-Low Power State on Clock Lane.<br>This active-High signal is asserted to cause a clock lane module to enter the ULP state. The lane module remains in this mode until txulpsclk is deasserted.                                                                                                                                                                                                            |
| cl_txulpsexit | Input     | core_clk     | Transmit ULP Exit Sequence.<br>This active-High signal is asserted when the ULP state is active and the protocol is ready to leave the ULP state. The PHY leaves the ULP state and begins driving Mark-1 after txulpsexit is asserted. The PHY later drives the Stop state (LP-11) when txrequestesc is deasserted. txulpsexit is synchronous to txclkesc. This signal is ignored when the lane is not in the ULP state. |

Table 6: D-PHY TX Data Lane High-Speed PPI Signals

| Signal              | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| txbyteclkhs         | Output    | N/A          | High-Speed Transmit Byte Clock.<br>This is used to synchronize PPI signals in the high-speed transmit clock domain. AMD recommends that all transmitting data lane modules share one txbyteclkhs signal. The frequency of txbyteclkhs is exactly 1/8 the high-speed bit rate.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| dl<n>_txdatahs[7:0] | Input     | txbyteclkhs  | High-Speed Transmit Data.<br>Eight-bit high-speed data to be transmitted. The signal connected to txdatahs[0] is transmitted first. Data is captured on rising edges of txbyteclkhs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| dl<n>_txrequesths   | Input     | txbyteclkhs  | High-Speed Transmit Request and Data Valid.<br>A Low-to-High transition on txrequesths causes the Lane module to initiate a SoT sequence. A High-to-Low transition on txrequest causes the lane module to initiate an EoT sequence. For data lanes, this active-High signal also indicates that the protocol is driving valid data on txdatahs to be transmitted. The lane module accepts the data when both txrequesths and txreadyhs are active on the same rising txbyteclkhs clock edge. The protocol always provides valid transmit data when txrequesths is active. After asserted, txrequesths remains High until the data has been accepted, as indicated by txreadyhs. txrequesths is only asserted while txrequestesc is Low. |
| dl<n>_txreadyhs     | Output    | txbyteclkhs  | High-Speed Transmit Ready.<br>This active-High signal indicates that txdatahs[7:0] is accepted by the Lane module to be serially transmitted. txreadyhs is valid on rising edges of txbyteclkhs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| dl<n>_txskewcalhs   | Input     | txbyteclkhs  | High-Speed Transmit Skew Calibration.<br>A low-to-high transition on TxSkewCalHS causes the lane module to initiate a deskew calibration. A high-to-low transition on TxSkewCalHS causes the lane module to stop deskew pattern transmission and initiate an EoT sequence<br><br><b>Note:</b> This pin is applicable only when the line rate is >1500 and the transmission of calibration packet is selected.                                                                                                                                                                                                                                                                                                                           |

Table 7: D-PHY TX Data Lane Control Interface PPI Signal

| Signal                | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                            |
|-----------------------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dl<n>_forcetxstopmode | Input     | Aync         | Force Lane to Generate Stop State.<br>This signal allows the protocol to force a lane module into the Stop state during initialization or following an error situation, such as an expired timeout. When this signal is High, the lane module state machine is immediately forced into the Stop state. |

Table 8: D-PHY TX Data Lane Escape Mode PPI Signals

| Signal             | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| txclkesc           | Input     | N/A          | Escape Mode Transmit Clock.<br>This clock is directly used to generate escape sequences. The period of this clock determines the phase times for low-power signals as defined in the D-PHY specification.                                                                                                                                                                                                                |
| dl<n>_txrequestesc | Input     | txclkesc     | Escape Mode Transmit Request. This active-High signal, asserted together with exactly one of txlpdtesc, txulpsesc, or one bit of txtriggeresc, is used to request entry into escape mode. When in escape mode, the lane stays in escape mode until txrequestesc is deasserted. txrequestesc is only asserted by the protocol while txrequesths is Low. txrequesths has highest priority than txrequestesc.               |
| dl<n>_txlpdtesc    | Input     | txclkesc     | Escape Mode Transmit Low-Power Data.<br>This active-High signal is asserted with txrequestesc to cause the lane module to enter low-power data transmission mode. The Lane module remains in this mode until txrequestesc is deasserted. txulpsesc and all bits of txtriggeresc[3:0] are Low when txlpdtesc is asserted.                                                                                                 |
| dl<n>_txulpsexit   | Input     | txclkesc     | Transmit ULP Exit Sequence.<br>This active-High signal is asserted when the ULP state is active and the protocol is ready to leave the ULP state. The PHY leaves the ULP state and begins driving Mark-1 after txulpsexit is asserted. The PHY later drives the Stop state (LP-11) when txrequestesc is deasserted. txulpsexit is synchronous to txclkesc. This signal is ignored when the lane is not in the ULP state. |
| dl<n>_txulpsesc    | Input     | txclkesc     | Escape Mode Transmit Ultra-Low Power State.<br>This active-High signal is asserted with txrequestesc to cause the lane module to enter the ultra-low power state. The lane module remains in this mode until txrequestesc is deasserted. txlpdtesc and all bits of txtriggeresc[3:0] are Low when txulpsesc is asserted.                                                                                                 |

Table 8: D-PHY TX Data Lane Escape Mode PPI Signals (cont'd)

| Signal                  | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dl<n>_txtriggeresc[3:0] | Input     | txclkesc     | <p>Escape Mode Transmit Trigger 0-3.</p> <p>One of these active-High signals is asserted with txrequestesc to cause the associated trigger to be sent across the lane interconnect. In the receiving lane module, the same bit of rxtriggeresc is then asserted and remains asserted until the lane interconnect returns to the Stop state, which happens when txrequestesc is deasserted at the transmitter. Only one bit of txtriggeresc[3:0] is asserted at any given time, and only when txlpdtesc and txulpdesc are both Low. The following mapping is done by the D-PHY TX module:</p> <ul style="list-style-type: none"> <li>Reset-Trigger → txtriggeresc[3:0] = 4'b0001</li> <li>Unknown-3 → txtriggeresc[3:0] = 4'b0010</li> <li>Unknown-4 → txtriggeresc[3:0] = 4'b0100</li> <li>Unknown-5 → txtriggeresc[3:0] = 4'b1000</li> </ul> |
| dl<n>_txdataesc[7:0]    | Input     | txclkesc     | <p>Escape Mode Transmit Data.</p> <p>This is the eight-bit Escape mode data to be transmitted in low-power data transmission mode. The signal connected to txdataesc[0] is transmitted first. Data is captured on rising edges of txclkesc.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| dl<n>_txvalidesc        | Input     | txclkesc     | <p>Escape Mode Transmit Data Valid.</p> <p>This active-High signal indicates that the protocol is driving valid data on txdataesc[7:0] to be transmitted. The lane module accepts the data when txrequestesc, txvalidesc, and txreadyesc are all active on the same rising txclkesc clock edge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| dl<n>_erresc       | Output    | Async        | Escape Entry Error.<br>If an unrecognized escape entry command is received, this active-High signal is asserted and remains asserted until the next change in line state.                                                                                                                                                             |
| dl<n>_errsyncesc   | Output    | Async        | Low-Power Data Transmission Synchronization Error.<br>If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, this active-High signal is asserted and remains asserted until the next change in line state.                                                        |
| dl<n>_errcontrol   | Output    | Async        | Control Error.<br>This active-High signal is asserted when an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in line state. |

## Clocking and Reset Signals

Included in the example design sources are circuits for clock and reset management. The following table shows the ports on the core that are associated with system clock and reset.

Table 14: Clocking and Reset Signals

| Signal           | Direction | Clock Domain | Description                                                                                                                                           |
|------------------|-----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| core_clk         | Input     | N/A          | A stable core clock used for control logic.                                                                                                           |
| core_rst         | Input     | core_clk     | An active-High reset signal.                                                                                                                          |
| system_rst_out   | Output    | core_clk     | An active-High system reset output to be used by the example design level logic. This port is available when Shared Logic is in the Core is selected. |
| mmcm_lock_out    | Output    | Async        | MMCM lock indication. This port is not available when shared logic in the core is selected in D-PHY TX Configuration.                                 |
| pll_lock_out     | Output    | Async        | PLL lock indication. This port is available when Shared Logic is in the Core is selected. This port is available for UltraScale+ families.            |
| system_rst_in    | Input     | core_clk     | System level reset. This port is available when Shared Logic is in Example Design is selected in D-PHY TX configuration.                              |
| pll_lock_in      | Input     | Async        | PLL lock indication. This port is available when Shared Logic is in Example Design is selected. This port is available for UltraScale+ families.      |
| ssc_byteclkhs_in | Input     | N/A          | SSC enabled clock input when the example design is in the core and the line rate is greater than 2500 Mb/s.                                           |

Table 14: Clocking and Reset Signals (cont'd)

| Signal               | Direction | Clock Domain               | Description                                                                                                                   |
|----------------------|-----------|----------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| spltdl<>_rxbyteclkhs | Input     | N/A                        | Clock for input splitter interface.<br><b>Note:</b> This pin is only available when splitter bridge mode is enabled.          |
| init_done            | Output    | core_clk                   | An active-High signal which indicates lane initialization is done.                                                            |
| ext_mmcm_clk_in      | Input     | External mmcm clock input. | When the External MMCM option is selected. Only applicable for SLAVE MODE and for UltraScale+ devices with Line rates > 1500. |
| ext_mmcm_lock_in     | Input     | External mmcm lock input.  | When the External MMCM option is selected. Only applicable for SLAVE MODE and for UltraScale+ devices with Line rates > 1500. |
| ext_mmcm_clk_out     | Output    | mmcm clock output.         | When the Internal MMCM option is selected. Only applicable for SLAVE MODE and for UltraScale+ devices with Line rates > 1500. |
| ext_mmcm_lock_out    | Output    | mmcm lock output.          | When the Internal MMCM option is selected. Only applicable for SLAVE MODE and for UltraScale+ devices with Line rates > 1500. |

## I/O Interface Signals

The example design includes circuits for PHY management and D-PHY compatible I/O connectivity. The following table shows the core ports that are associated with the I/O interface.

Table 15: D-PHY TX I/O Interface

| Signal                         | Direction | Clock Domain | Description                                                                                                         |
|--------------------------------|-----------|--------------|---------------------------------------------------------------------------------------------------------------------|
| clk_txp                        | Output    | N/A          | Positive differential serial data output pin for clock lane. Available only for UltraScale+, Versal Adaptive SoC.   |
| clk_txn                        | Output    | N/A          | Negative differential serial data output pin for clock lane. Available only for UltraScale+, Versal Adaptive SoC.   |
| data_txp[<n-1>:0] <sup>1</sup> | Output    | N/A          | Positive differential serial data output pin for data lane(s). Available only for UltraScale+, Versal Adaptive SoC. |
| data_txn[<n-1>:0] <sup>1</sup> | Output    | N/A          | Negative differential serial data output pin for data lane(s). Available only for UltraScale+, Versal Adaptive SoC. |
| clk_hs_txp                     | Output    | N/A          | High-Speed positive differential serial data output pin for clock lane. Available only for 7 series FPGA families.  |
| clk_hs_txn                     | Output    | N/A          | High-Speed negative differential serial data output pin for clock lane. Available only for 7 series FPGA families.  |
| clk_lp_txp                     | Output    | N/A          | Low-Power positive serial data output pin for clock lane. Available only for 7 series FPGA families.                |
| clk_lp_txn                     | Output    | N/A          | Low-Power negative serial data output pin for clock lane. Available only for 7 series FPGA families.                |

Table 15: D-PHY TX I/O Interface (cont'd)

| Signal                            | Direction | Clock Domain | Description                                                                                                          |
|-----------------------------------|-----------|--------------|----------------------------------------------------------------------------------------------------------------------|
| data_hs_txp[<n-1>:0] <sup>1</sup> | Output    | N/A          | High-Speed positive differential serial data output pin for data lane(s). Available only for 7 series FPGA families. |
| data_hs_txn[<n-1>:0] <sup>1</sup> | Output    | N/A          | High-Speed negative differential serial data output pin for data lane(s). Available only for 7 series FPGA families. |
| data_lp_txp[<n-1>:0] <sup>1</sup> | Output    | N/A          | Low-Power positive serial data output pin for data lane(s). Available only for 7 series FPGA families.               |
| data_lp_txn[<n-1>:0] <sup>1</sup> | Output    | N/A          | Low-Power negative serial data output pin for data lane(s). Available only for 7 series FPGA families.               |

**Notes:**

1. <n> is the data lane number.

Table 16: D-PHY RX I/O Interface

| Signal                            | Direction | Clock Domain | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-----------------------------------|-----------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| clk_rxp                           | Input     | N/A          | Positive differential serial data input pin for clock lane. Available only for UltraScale+, Versal Adaptive SoC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| clk_rxn                           | Input     | N/A          | Negative differential serial data input pin for clock lane. Available only for UltraScale+, Versal Adaptive SoC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| data_rxp[<n-1>:0] <sup>1</sup>    | Input     | N/A          | Positive differential serial data input pin for data lane(s). Available only for UltraScale+, Versal Adaptive SoC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| data_rxn[<n-1>:0] <sup>1</sup>    | Input     | N/A          | Negative differential serial data input pin for data lane(s). Available only for UltraScale+, Versal Adaptive SoC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

The core infers bitslice0 of a nibble for strobe propagation within the byte group; &lt;x&gt; indicates byte group (0,1,2,3); &lt;y&gt; indicates bitslice0 position (0 for the lower nibble, 6 for the upper nibble.)</p> <ul style="list-style-type: none"> <li>• RTL Design: There is no need to drive any data on these ports.</li> <li>• IP integrator: These ports must be brought to the top level of the design in order for the constraints to be properly applied.</li> </ul> <p><b>Note:</b> Pins are available only for UltraScale+ families.</p> |
| clk_hs_rxp                        | Input     | N/A          | High-Speed positive differential serial data input pin for clock lane. Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| clk_hs_rxn                        | Input     | N/A          | High-Speed negative differential serial data input pin for clock lane. Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| clk_lp_rxp                        | Input     | N/A          | Low-Power positive serial data input pin for clock lane. Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| clk_lp_rxn                        | Input     | N/A          | Low-Power negative serial data input pin for clock lane. Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data_hs_rxp[<n-1>:0] <sup>1</sup> | Input     | N/A          | High-Speed positive differential serial data input pin for data lane(s). Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| data_hs_rxn[<n-1>:0] <sup>1</sup> | Input     | N/A          | High-Speed negative differential serial data input pin for data lane(s). Available only for 7 series FPGA families.                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 16: D-PHY RX I/O Interface (cont'd)

| Signal                            | Direction | Clock Domain | Description                                                                                           |
|-----------------------------------|-----------|--------------|-------------------------------------------------------------------------------------------------------|
| data_lp_rxp[<n-1>:0] <sup>1</sup> | Input     | N/A          | Low-Power positive serial data input pin for data lane(s). Available only for 7 series FPGA families. |
| data_lp_rxn[<n-1>:0] <sup>1</sup> | Input     | N/A          | Low-Power negative serial data input pin for data lane(s). Available only for 7 series FPGA families. |

**Notes:**

1. <n> is the data lane number.

## AXI4-Lite Interface Signals

The AXI4-Lite signals (*s\_axi\_\**) are described in the *Vivado Design Suite: AXI Reference Guide* ([UG1037](#)).

## 7 Series FPGA Families Calibration Logic Signals

D-PHY RX IP includes calibration logic for 7 series FPGA families. The following table lists ports associated with the calibration logic.

Table 17: 7 Series FPGA Families Calibration Logic Signals

| Signal          | Direction | Clock Domain | Description                                                                                                              |
|-----------------|-----------|--------------|--------------------------------------------------------------------------------------------------------------------------|
| dlyctrl_rdy_out | Output    | N/A          | Ready signal output from IDEALYCTRL, stating delay values are adjusted as per vtc changes.                               |
| dlyctrl_rdy_in  | Input     | N/A          | Ready signal input to IDELAYCTRL See 'Include IDELAYCTRL in Core' in the <a href="#">Core Configuration Tab</a> section. |

## Active Lane Support Signals

D-PHY TX IP supports active lanes. The following table lists ports associated with active lane support.

Table 18: Active Lane Support Signal

| Signal                                | Direction | Clock Domain | Description                                                                                                                                              |
|---------------------------------------|-----------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| active_lanes_in[<n-1>:0] <sup>1</sup> | Input     | core_clk     | Input to specify active lanes. This feature is available for D-PHY TX multi-lane configuration. Bits from LSB to MSB corresponds to TX Data lane 0 to 3. |

**Notes:**

1. <n> is the data lane number.

## Register Space

The MIPI D-PHY core register space is shown in the following table. This register interface is optional and allows you to access the general interconnect states. It also provides control to program protocol timing parameters, such as INIT, and the protocol watchdog timers.

**IMPORTANT!** This memory space must be aligned to an AXI 32-bit word boundary.

## Endianness Details

All registers are in little endian format, as shown in the following table.

Table 19: 32-bit Little Endian Example

| Byte   | Address Offset | Bit Boundaries |
|--------|----------------|----------------|
| Byte 0 | 0x0            | [7:0]          |
| Byte 1 | 0x1            | [15:8]         |
| Byte 2 | 0x2            | [23:16]        |
| Byte 3 | 0x3            | [31:24]        |

Table 20: MIPI D-PHY Core Register Space

| Offset | Name             | Width  | Access | Description                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------|--------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0    | CONTROL          | 32-bit | R/W    | Enable and soft reset control for PHY.                                                                                                                                                                                                                                                                                                                                                                                                       |
| 0x4    | IDELAY_TAP_VALUE | 32-bit | R/W    | To program the tap values in fixed mode of calibration in 7 series D-PHY RX configuration for lanes 1 to 4.                                                                                                                                                                                                                                                                                                                                  |
| 0x8    | INIT             | 32-bit | R/W    | Initialization timer.                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0xC    | Reserved         | 32-bit | N/A    | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 0x10   | HS_TIMEOUT       | 32-bit | R/W    | Watchdog timeout in high-speed mode. Time from SoT to EoT is taken into account for the timer elapse. This register is available if the <b>Enable HS and ESC Timeout Counters/Registers</b> checkbox is selected in the Vivado IDE. HS_RX_TIMEOUT is used for RX (slave) HS_TX_TIMEOUT is used for TX (master)                                                                                                                               |
| 0x14   | ESC_TIMEOUT      | 32-bit | R/W    | Protocol specific. In escape mode, if line stays in LP-00 longer than this time period the core generates a timeout and goes to Stop state. This register is available if the <b>Enable HS and ESC Timeout Counters/Registers</b> checkbox is selected in the Vivado IDE. This register is used as Escape Mode Timeout in RX, and Escape Mode Silence Timeout in TX. Escape Mode Timeout should be greater than Escape Mode Silence Timeout. |
| 0x18   | CL_STATUS        | 32-bit | RO     | Status register for PHY error reporting for clock Lane.                                                                                                                                                                                                                                                                                                                                                                                      |

Table 20: MIPI D-PHY Core Register Space (cont'd)

| Offset       | Name             | Width  | Access | Description                                                                                                 |
|--------------|------------------|--------|--------|-------------------------------------------------------------------------------------------------------------|
| 0x1C to 0x28 | DL0_STATUS       | 32-bit | RO     | Status registers for PHY error reporting for data lanes 1 to 4.                                             |
|              | DL1_STATUS       | 32-bit | RO     |                                                                                                             |
|              | DL2_STATUS       | 32-bit | RO     |                                                                                                             |
|              | DL3_STATUS       | 32-bit | RO     |                                                                                                             |
| 0x30         | HS_SETTLE        | 32-bit | R/W    | HS_SETTLE timing control for lane 1.                                                                        |
| 0x34 to 0x44 | Reserved         | 32-bit | N/A    | N/A                                                                                                         |
| 0x48 to 0x60 | HS_SETTLE        | 32-bit | R/W    | HS_SETTLE timing control for lanes 2 to 8.                                                                  |
| 0x64 to 0x70 | DL4_STATUS       | 32-bit | RO     | Status registers for PHY error reporting for data lanes 5 to 8.                                             |
|              | DL5_STATUS       | 32-bit | RO     |                                                                                                             |
|              | DL6_STATUS       | 32-bit | RO     |                                                                                                             |
|              | DL7_STATUS       | 32-bit | RO     |                                                                                                             |
| 0x74         | IDELAY_TAP_VALUE | 32-bit | R/W    | To program the tap values in fixed mode of calibration in 7 series D-PHY RX configuration for lanes 5 to 8. |

## CONTROL Registers

The following table shows the CONTROL register (0x0 offset) bit mapping and description. Writing a 1 to SRST resets the MIPI D-PHY core. For the soft reset impact on the MIPI D-PHY core, see [Reset Coverage](#) table. The MIPI D-PHY core functions only when the DPHY\_EN bit is set to 1 (by default).

Table 21: CONTROL Register Bit Description

| Bits | Name     | Access | Default Value | Description                                                                                                                        |
|------|----------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------|
| 31:2 | Reserved | RO     | 0             | Reserved.                                                                                                                          |
| 1    | DPHY_EN  | R/W    | 1             | Enable bit for D-PHY.<br><br>1: D-PHY controller is enabled.<br>0: D-PHY controller is disabled.                                   |
| 0    | SRST     | R/W    | 0             | Soft reset for D-PHY Controller.<br>If 1 is written to this bit, the D-PHY controller fabric logic and status registers are reset. |

## IDELAY\_TAP\_VALUE for Lanes 1 to 4

The IDELAY Tap Value register (0x4 Offset) is used to configure the idelay tap values in fixed mode for 7 series families. The tap values are programmed dynamically during the core operation. The core need not be disabled to program a different tap value. The initial tap value for all lanes is same as the GUI parameter C\_IDLY\_TAP. The following table shows the Idelay Tap Value register bit description.

Table 22: IDELAY\_TAP VALUE Bit Description

| Bits  | Name                | Access | Default                   | Description                             |
|-------|---------------------|--------|---------------------------|-----------------------------------------|
| 31:29 | Reserved            | RO     | 0                         | Reserved                                |
| 28:24 | Tap value for lane3 | R/W    | IDELAY tap value from GUI | Programs the IDELAY tap value for lane3 |
| 23:21 | Reserved            | RO     | 0                         | Reserved                                |
| 20:16 | Tap value for lane2 | R/W    | IDELAY tap value from GUI | Programs the IDELAY tap value for lane2 |
| 15:13 | Reserved            | RO     | 0                         | Reserved                                |
| 12:8  | Tap value for lane1 | R/W    | IDELAY tap value from GUI | Programs IDELAY Tap value for lane1     |
| 7:5   | Reserved            | RO     | 0                         | Reserved                                |
| 4:0   | Tap value for lane0 | R/W    | IDELAY tap value from GUI | Programs IDELAY Tap value for lane0     |

**Notes:**

1. All lanes tap values are available for R/W irrespective of the GUI configuration for number of lanes.

## INIT Register

The INIT register (0x8 offset) is used for lane initialization. The following table shows the register bit description.

**RECOMMENDED:** AMD recommends that you use one millisecond or longer as  $T_{INIT}$  for the MIPI D-PHY TX core, and 100  $\mu s$  for the MIPI D-PHY RX core.

Table 23: INIT Register Bit Description

| Bits | Name   | Access | Default Value                                                         | Description                       |
|------|--------|--------|-----------------------------------------------------------------------|-----------------------------------|
| 31:0 | T_INIT | R/W    | RX D-PHY IP: 100 $\mu s$ (32'h186A0)<br>TX D-PHY IP: 1 ms (32'hF4240) | Initialization timer value in ns. |

## HS\_TIMEOUT Register

The HS\_TIMEOUT register (0x10 offset) is used as a watchdog timer in high-speed mode. This register is used as HS\_TX\_TIMEOUT (MIPI D-PHY TX core) or as HS\_RX\_TIMEOUT (MIPI D-PHY RX core). The following table shows the HS\_TIMEOUT register bit description.

Table 24: HS\_TIMEOUT Register Bit Description

| Bits | Name                        | Access | Default Value | Description                                                                                                                                                                                                                                |
|------|-----------------------------|--------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | HS_RX_TIMEOUT/HS_TX_TIMEOUT | R/W    | 65,541        | Maximum frame length in bytes. Valid range is 1,000 to 65,541. Timeout occurs for HS_RX_TIMEOUT/D-PHY_LANES at the RX data lanes in high speed mode. Timeout occurs for HS_TX_TIMEOUT/D-PHY_LANES at the TX data lanes in high speed mode. |

## ESC\_TIMEOUT Register

The ESC\_TIMEOUT register (0x14 offset) is used for the watchdog timer in escape mode. The following table shows the ESC\_TIMEOUT register bit description.

Table 25: ESC\_TIMEOUT Register Bit Description

| Bits | Name        | Access | Default Value | Description                                                                    |
|------|-------------|--------|---------------|--------------------------------------------------------------------------------|
| 31:0 | ESC_TIMEOUT | R/W    | 25,600 ns     | Escape timeout period in ns. Timeout occurs for the data lanes in escape mode. |

## CL\_STATUS Register

CL\_STATUS register (0x18 offset) provides clock lane status and state machine control. The following table provides CL\_STATUS register bit description.

Table 26: CL\_STATUS Register Bit Description

| Bits | Name        | Access | Default Value | Description                                                                                                                                                                                                                                                                                                     |
|------|-------------|--------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:6 | Reserved    | RO     | 0             | Reserved                                                                                                                                                                                                                                                                                                        |
| 5    | ERR_CONTROL | RO     | 0             | Clock lane control error. This bit is applicable only for the MIPI D-PHY RX core. This bit is asserted when D-PHY RX clock lane receives erroneous High-Speed entry sequence or ULPS entry sequence or ULPS exit sequence. This bit is cleared when D-PHY RX clock lane receives stopstate on the serial lines. |
| 4    | STOP_STATE  | RO     | 0             | Clock lane is in the Stop state.                                                                                                                                                                                                                                                                                |
| 3    | INIT_DONE   | RO     | 0             | Set after the lane has completed initialization.                                                                                                                                                                                                                                                                |
| 2    | ULPS        | RO     | 0             | Set to 1 when the core in ULPS (ULP State) mode.                                                                                                                                                                                                                                                                |
| 1:0  | MODE        | RO     | 0             | 2'b00: Low Power Mode (Control Mode)<br>2'b01: High Speed Mode<br>2'b10: Escape Mode                                                                                                                                                                                                                            |

## DL\_STATUS Register

The DL\_STATUS register (0x1C to 0x28, 0x64 to 0x70 offset) provides data lane status and state machine control. The following table provides the DL\_STATUS register bit description.

Table 27: DL\_STATUS Register Bit Description

| Bits  | Name     | Access | Default Value | Description                                                                                                                                                                                                                                                                           |
|-------|----------|--------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | PKT_CNT  | RO     | 0             | Number of packets received or transmitted on the data lane. This field is updated using the rxbyteclkhs clock and the RX clock lane must be in high-speed mode when reset is applied to the D-PHY RX IP. Otherwise, this value does not get reset for MIPI D-PHY RX IP configuration. |
| 15:7  | Reserved | RO     | 0             | Reserved.                                                                                                                                                                                                                                                                             |

Table 27: DL\_STATUS Register Bit Description (cont'd)

| Bits | Name       | Access | Default Value | Description                                                                                                                                                                  |
|------|------------|--------|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 6    | STOP_STATE | RO     | 0             | Data lane is in the Stop state.                                                                                                                                              |
| 5    | ESC_ABORT  | R/W1C  | 0             | This bit is set after the Data Lane Escape Timeout (Escape Mode Timeout in case of RX, or Escape Mode Silence Timeout in case of TX) is elapsed. Write-to-1 clears this bit. |
| 4    | HS_ABORT   | R/W1C  | 0             | Set after the Data Lane High-Speed Timeout (HS_TX_TIMEOUT or HS_RX_TIMEOUT) has elapsed. Write to 1 clears this bit.                                                         |
| 3    | INIT_DONE  | RO     | 0             | Set after the lane has completed initialization.                                                                                                                             |
| 2    | ULPS       | RO     | 0             | Set to 1 when the core is in ULPS mode.                                                                                                                                      |
| 1:0  | MODE       | RO     | 0             | 2'b00: Low Power mode (control mode).<br>2'b01: High Speed mode<br>2'b10: Escape mode.                                                                                       |

## HS\_SETTLE Register

The HS\_SETTLE register (0x30 offset, 0x48 to 0x60 offset) provides control to update the HS\_SETTLE timing parameter for RX data lanes. The following table provides the HS\_SETTLE register bit description.

Table 28: HS\_SETTLE Register Bit Description

| Bits | Name         | Access | Default Value | Description                                                                                                                                                                                                                                                                                                                                                 |
|------|--------------|--------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:9 | Reserved     | RO     | 0             | Reserved                                                                                                                                                                                                                                                                                                                                                    |
| 8:0  | HS_SETTLE_NS | R/W    | 135 + 10 UI   | HS_SETTLE timing parameter in the number of core_clk clocks. For example, to program 105 ns, then the value that needs to be programmed is 105/5, that is, 21 (here 5 is 5 ns, that is, the time period of core_clk). This value is applied for all data lanes and will only be applicable for D-PHY RX configuration.<br><b>Note:</b> UI is unit interval. |

## IDELAY\_TAP\_VALUE for Lanes 5 to 8

The IDELAY Tap Value register (0x74 Offset) is used to configure the IDELAY tap values in fixed mode for 7 series FPGAs. The tap values are programmed dynamically during the core operation. The core need not be disabled to program a different tap value. The initial tap value for all lanes is same as the GUI parameter C\_IDLY\_TAP. The following table shows the Idelay Tap Value register bit description.

Table 29: IDELAY\_TAP VALUE Bit Description

| Bits  | Name     | Access | Default | Description |
|-------|----------|--------|---------|-------------|
| 31:29 | Reserved | RO     | 0       | Reserved    |

Table 29: IDELAY\_TAP VALUE Bit Description (cont'd)

| Bits  | Name                | Access | Default                   | Description                             |
|-------|---------------------|--------|---------------------------|-----------------------------------------|
| 28:24 | Tap value for lane7 | R/W    | IDELAY tap value from GUI | Programs the IDELAY tap value for lane7 |
| 23:21 | Reserved            | RO     | 0                         | Reserved                                |
| 20:16 | Tap value for lane6 | R/W    | IDELAY tap value from GUI | Programs the IDELAY tap value for lane6 |
| 15:13 | Reserved            | RO     | 0                         | Reserved                                |
| 12:8  | Tap value for lane5 | R/W    | IDELAY tap value from GUI | Programs IDELAY Tap value for lane5     |
| 7:5   | Reserved            | RO     | 0                         | Reserved                                |
| 4:0   | Tap value for lane4 | R/W    | IDELAY tap value from GUI | Programs IDELAY Tap value for lane4     |

**Notes:**

1. All lanes tap values are available for R/W irrespective of the GUI configuration for number of lanes.

# Designing with the Core

This chapter includes guidelines and additional information to facilitate designing with the core.

## General Design Guidelines

This section describes the steps required to turn a MIPI D-PHY core into a fully functioning design with user-application logic.

**IMPORTANT!** *Not all implementations require all of the design steps listed here. Follow the logic design guidelines in this manual carefully.*

When there are multiple instances of MIPI interfaces or other IP sharing the same IO bank, initialize all interfaces in the same HP IO bank at the same time. This includes resetting all instances at the same time. When there are multiple DPHY TX instances, you cannot mix MIPI D-PHY TX with lane-rate ( $>1501$  Mb/s and  $\leq 1500$  Mb/s) in the same HP IO bank. For more information on implementing multiple interfaces in the same HP IO Bank, see the *UltraScale Architecture SelectIO Resources User Guide* ([UG571](#)).

## Use the Example Design

Each instance of the MIPI D-PHY v4.3 core created by the Vivado design tool is delivered with an example design that can be implemented in a device and then simulated. This design can be used as a starting point for your own design or can be used to sanity-check your application in the event of difficulty. See the Example Design content for information about using and customizing the example designs for the core.

## Know the Degree of Difficulty

The MIPI D-PHY core design is challenging to implement in any technology, and the degree of difficulty is further influenced by:

- Maximum system clock frequency
- Targeted device architecture
- Nature of the user application

All MIPI D-PHY core implementations require careful attention to system performance requirements. Pipelining, logic mappings, placement constraints, and logic duplications are all methods that help boost system performance.

## Registering Signals

To simplify timing and increase system performance in a programmable device design, keep all inputs and outputs registered between the user application and the core. This means that all inputs and outputs from the user application should come from, or connect to, a flip-flop. While registering signals might not be possible for all paths, it simplifies timing analysis and makes it easier for the AMD tools to place and route the design.

## Recognize Timing Critical Signals

The constraints provided with the example design identify the critical signals and timing constraints that should be applied.

## Make Only Allowed Modifications

You should not modify the core. Any modifications can have adverse effects on system timing and protocol compliance. Supported user configurations of the core can only be made by selecting the options in the customization IP dialog box when the core is generated.

## I/O Placement

The MIPI D-PHY protocol supports the MIPI\_DPHY\_DCI I/O standard, and this I/O standard is supported only in the HP I/O bank in AMD UltraScale+™ and AMD Zynq™ UltraScale+™ MPSoC devices and in the XPIO bank in AMD Versal™ Adaptive SoCs. It is recommended that you use consecutive bit slices for data lanes starting from the clock lane BITSlice. All I/O placements should be restricted to the same I/O bank.

---

## Shared Logic

Shared Logic provides a flexible architecture that works both as a stand-alone core and as part of a larger design with one or more core instances. This minimizes the amount of HDL modifications required, but at the same time retains the flexibility of the core.

There is a level of hierarchy called `<component_name>_support`. The following figures show two hierarchies where the shared logic is either contained in the core or in the example design. In these figures, `<component_name>` is the name of the generated core. The difference between the two hierarchies is the boundary of the core. It is controlled using the Shared Logic option in the Vivado IDE Shared Logic tab for the MIPI D-PHY Controller.

Figure 11: Shared Logic Included in Core

Figure 12: Shared Logic Included in Example Design

The shared logic comprises an MMCM, a PLL and some BUFGs (maximum of four).

## Shared Logic in Core

Select Include Shared Logic in core if:

- You do not require direct control over the MMCM and PLL generated clocks
- You want to manage multiple customizations of the core for multi-core designs
- This is the first MIPI D-PHY core in a multi-core system

These components are included in the core, and their output ports are also provided as core outputs.

For SLAVE Mode with line rates of over 1500, and when you select Including Shared logic in the core.

Selecting Internal MMCM implements MMCM inside the core.

Selecting External MMCM does not implement the MMCM inside the core.

Required clocks need to be generated from the external MMCM and need to be connected to the core.

## Shared Logic in Example Design

Select Include Shared Logic in example design if:

- There should be at least one MIPI D-PHY IP with Include shared Logic in the Core mode whose outputs for shared resources can be used in other MIPI D-PHY IP generated with Include shared logic in example design mode.
- This is the second MIPI D-PHY core in a multi-core design
- You only want to manage one customization of the MIPI D-PHY core in your design
- You want direct access to the input clocks

To fully use the MMCM and PLL, customize one MIPI D-PHY core with shared logic in the core and one with shared logic in the example design. You can connect the MMCM/PLL outputs from the first MIPI D-PHY core to the second core.

If you want fine control you can select **Include shared logic in example design** and base your own logic on the shared logic produced in the example design.

Following things should also be taken into consideration while connecting Master & Slave cores:

1. Master and slave cores should have the same CLKOUTPHY clock frequency.
2. TX master and slave cores should be configured with the same line rate when sharing clock resources.

3. RX master and slave cores with line-rate 1500 Mb/s or less can share clock resources.
4. RX master and slave cores with the same line-rate (greater than 1500 Mb/s) can share clock resources.
5. Additionally MIPI D-PHY TX can share master/slave clock resources, only if the TXCLKESC is configured with the same clock frequency.

## Case 1: UltraScale+ Device MIPI D-PHY TX Core (Line Rates above 600 Mb/s)

The following figure shows the sharable resource connections from the MIPI D-PHY TX core with shared logic included (DPHY\_TX\_MASTER) to the instance of another MIPI D-PHY TX core without shared logic (DPHY\_TX\_SLAVE) and the line rate is above 600 Mb/s.

Figure 13: Shared Logic Example for MIPI D-PHY TX Core (Line Rate above 600 Mb/s)

X15950-021716

## Case 2: UltraScale+ Device MIPI D-PHY RX Core

The following figure shows the sharable resource connections from the MIPI D-PHY RX core with shared logic included (DPHY\_RX\_MASTER) to the instance of another MIPI D-PHY RX core without shared logic (DPHY\_RX\_SLAVE).

Figure 14: Shared Logic Example for MIPI D-PHY RX Core

X15951-021517

## Case 3: 7 Series FPGAs MIPI D-PHY TX Core

The following figure shows the sharable resource connections from the MIPI D-PHY TX core with shared logic included (DPHY\_TX\_MASTER) to the instance of another MIPI D-PHY TX core without shared logic (DPHY\_TX\_SLAVE).

Figure 15: Shared Logic Example for 7 Series FPGAs MIPI D-PHY TX Core

## Case 4: UltraScale+ Device MIPI D-PHY TX Core (Line rates below 600 Mb/s)

The following figure shows the sharable resource connections from the MIPI D-PHY TX core with shared logic included (DPHY\_TX\_MASTER) to the instance of another MIPI D-PHY TX core without shared logic (DPHY\_TX\_SLAVE) and selected line rate is below 600 Mb/s.

Figure 16: Shared Logic Example for MIPI D-PHY TX Core (Line Rate below 600 Mb/s)

## I/O Planning for UltraScale+ Devices

The MIPI D-PHY Controller provides an I/O planner feature for I/O selection. You can select any I/O for the clock and data lanes in the TX core configuration for the selected HP I/O bank.

For the RX core configuration, dedicated byte clocks (DBC) or quad byte clocks (QBC) are listed for the clock lane for the selected HP I/O bank. For the QBC clock lane all of the I/O pins are listed for data lane I/O selection but for the DBC clock lane only byte group I/O pins are listed for data lane I/O selection in the RX core configuration.

Eight D-PHY IP cores can be implemented per IO bank due to BITSlice and BITSlice\_CONTROL instances in UltraScale+ devices.

**IMPORTANT!** If the RX data lane I/O pins are selected non-contiguously then an additional one, two, or three I/O pins (RX\_BITSlice) are automatically used for clock/Strobe propagation. Therefore, it is recommended that you select adjacent I/O pins for the RX configuration to make efficient use of the I/O. The propagation of strobes to the RX data pins follows the inter-byte and inter-nibble clocking rules given in the UltraScale Architecture SelectIO Resources User Guide (UG571).

## I/O Planning for Versal Devices

The MIPI D-PHY GUI does not have I/O Assignment tab for Versal devices. Instead you need to use consolidated I/O planning in the main Vivado IDE Planning that is nibble planner. You can select any I/O for the clock and data lanes in the TX core configuration for the selected XPIO bank.

**Table 30: IO Selection for TX Mode depending on Parameters**

| Line-rate (Mb/s) | D-PHY IP Parameter<br>C_EN_DCTS_LOGIC<br>(Guarantees the clock Rising<br>Edge Alignment to first payload<br>bit on serial lines) | IO Guidelines                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------|----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| >2500            | Disabled (i.e., 0)                                                                                                               | <ul style="list-style-type: none"> <li><b>Clock Lane:</b> Select the Clock Capable pin, i.e., 0th pin of a Nibble.</li> <li><b>Data Lanes:</b> Select the data lanes such that the propagation of strobe to the TX data pins follows the inter-byte and inter-nibble clocking rules given in the "Clocking" section of <i>Versal Adaptive SoC SelectIO Resources Architecture Manual</i> (<a href="#">AM010</a>).</li> </ul>                                                       |
| >2500            | Enabled (i.e., 1)                                                                                                                | <ul style="list-style-type: none"> <li><b>Clock Lane:</b> Select the Clock Capable pin, i.e., 0th pin of a Nibble.</li> <li><b>Data Lanes:</b> Select the data lanes such they are not in the same Nibble as Clock lane Nibble &amp; the propagation of strobe to the TX data pins follows the inter-byte and inter-nibble clocking rules given in the "Clocking" section of <i>Versal Adaptive SoC SelectIO Resources Architecture Manual</i> (<a href="#">AM010</a>).</li> </ul> |
| <2500            | Disabled (i.e., 0)                                                                                                               | You can select any I/O for the clock and data lanes in the TX core configuration for the selected bank.                                                                                                                                                                                                                                                                                                                                                                            |
| <2500            | Enabled (i.e., 1)                                                                                                                | You can select any I/O for the clock and data lanes but the Clock Lane and Data Lanes should not be in the same Nibble.                                                                                                                                                                                                                                                                                                                                                            |

For the RX core configuration, select the clock capable pin that is 0th Pin ("XCC" and "GC/XCC" pins) of a nibble for the clock lane for the selected XPIO bank.

Select the data lane position depending upon the Clock lane Nibble for the RX core configuration, that is, in the nibble where the clock lane is present and adjacent nibble (Highly recommended). Following is the representation of 4 instances of 4 lane D-PHY in a Bank.

Figure 17: RX Core Configuration

Detailed steps on how to use the Vivado IDE Planning is detailed under section "I/O Planning for Versal Advanced IO Wizard" in *Advanced I/O Wizard LogiCORE IP Product Guide* ([PG320](#)).

While selecting the IOs in a bank across nibbles, users need to ensure the inter-nibble and inter-byte clock guidelines are followed. Refer to the "Clocking" section in *Versal Adaptive SoC SelectIO Resources Architecture Manual* ([AM010](#)).

The following figure shows the eight MIPI D-PHY RX cores configured with one clock lane and two data lanes and implemented in a single I/O bank.

The DPHY\_RX\_MASTER is configured by selecting the **Include Shared Logic in core** option and the remaining cores are configured by selecting **Include Shared Logic in example design**. The constant `clkoutphy` signal is generated within the PLL of the DPHY\_RX\_MASTER core irrespective of the line rate and shared with all other slave IP cores (DPHY\_RX\_SLAVE1 to DPHY\_RX\_SLAVE7) with different line rates. The `pll_lock` signal connection is required for slave IP initialization.

**Note:** When the master D-PHY RX line rate is < 1500 Mb/s, the slave D-PHY RX can be configured with any line rates < = 1500 Mb/s, but when the master D-PHY RX line rate is > 1500 Mb/s the slave RX should only be configured with matching line rate of master D-PHY RX.

Figure 18: MIPI D-PHY RX Core Shared Logic Use Case for Single I/O Bank

X15987-021716

## Clocking

The MIPI D-PHY Controller requires a 200 MHz free running clock (`core_clk`). This clock is used as input to the Mixed-Mode Clock Manager (MMCM), and the required clocks are generated based on IP configurations.

**IMPORTANT!** `core_clk` should be either coming from the on-board oscillator or the single MMCM or the PLL from target FPGA device. `core_clk` should not be generated from the cascaded MMCM blocks.

The following figures show the MIPI D-PHY Controller clock diagrams for supported families. The MIPI D-PHY TX core takes `core_clk` as an input and generates the necessary clocks from the MMCM. The `clkoutphy` signal from the PLL is used in the `BITSLICE_CONTROL` of the PHY block in native mode.

Figure 19: MIPI D-PHY Core TX Clocking for Versal Adaptive SoC

Figure 20: MIPI D-PHY Core TX Clocking for UltraScale+ Families

Figure 21: MIPI D-PHY Core RX Clocking for UltraScale+ and Versal Adaptive SoC where Line Rates  $\leq 1500$  Mb/s

**Note:** For line rates less than or equal to 1500 Mb/s, the frequency value is 1500. When line rates are greater than 1500 Mb/s, the frequency value is equal to the line rate.

Figure 22: MIPI D-PHY Core RX Clocking for UltraScale+ and Versal Adaptive SoC where Line Rates >1500 Mb/s

X24838-111820

**Note:** For line rates less than or equal to 1500 Mb/s, the frequency value is 1500. When line rates are greater than 1500 Mb/s, the frequency value is equal to the line rate.

The following figures show the MIPI D-PHY Controller clock diagrams for 7 series FPGA families. The MIPI D-PHY Controller takes `core_clk` as an input and generates the necessary clocks from the MMCM for D-PHY TX IP. MMCM is *not* used in the D-PHY RX IP when the line rate is less than or equal to 1500 Mb/s; for line rates greater than 1500 Mb/s, MMCM is used.

Figure 23: MIPI D-PHY Core TX Clocking for 7 Series FPGA Families

X17794-090116

Figure 24: MIPI D-PHY Core RX Clocking for 7 Series FPGA Families

| dl_tst_clk_in     | line rate/2 | 7 series FPGA families D-PHY TX configuration and Shared Logic is in the core and Infer OBUFTDS option is selected           | Used for TX data lane IO buffer tristate signal synchronization                                               |

**Notes:**

1. The `txbyteclkhs` and `xiphy_byteclk` clocks should be generated from same clock source or PLL.
2. Ratios for various line rate range are as follows:
  - 4 for 300 to 599 Mb/s.
  - 2 for 150 to 299 Mb/s.
  - 1 for 80 to 149 Mb/s.

For example, the `xiphy_byteclk` frequency is 125.000 MHz for 500 Mb/s line rate.

**IMPORTANT!** All the input clocks supplied to the MIPI D-PHY core should have  $\pm 100$  PPM difference and violating this results in either data corruption or data duplication.

## Resets

The active-High reset signal `core_rst` is used in the MIPI D-PHY Controller.

The following figure shows the power-on reset behavior for the MIPI D-PHY Controller.

1. The `core_rst` signal is asserted for forty `core_clk` cycles. Forty clock cycles are required to propagate the reset throughout the system.
2. The `mmcm_lock` and `pll_lock` signals go Low due to `core_rst` assertion.
3. The `mmcm_lock` signal is asserted within 100  $\mu$ s after `core_rst` deassertion and generates the input clock for the PLL.
4. The `pll_lock` signal is asserted within 100  $\mu$ s after `mmcm_lock` assertion.
5. LP-11 is driven on the lines for T\_INIT or longer. This helps the MIPI D-PHY core complete the lane initialization. Lane initialization is indicated by the `init_done` internal status signal in the waveform.
6. After LPX\_PERIOD of LP-11 assertion, `stopstate` is asserted.

Figure 25: Power on Reset Sequence for the MIPI D-PHY Core

The following table summarizes all resets available to the MIPI D-PHY Controller and the components affected by them.

Table 32: Reset Coverage

| Functional Block    | <code>core_rst</code> | DPHY_EN (Core Enable from Register) | SRST (Soft Reset from Register) | <code>s_axi_aresetn</code> |
|---------------------|-----------------------|-------------------------------------|---------------------------------|----------------------------|
| TX/RX PCS           | Yes                   | Yes                                 | Yes                             | No                         |
| TX/RX PHY           | Yes                   | Yes                                 | No                              | No                         |
| Registers           | Yes                   | Yes                                 | Yes                             | Yes                        |
| Lane Initialization | Yes                   | Yes                                 | No                              | No                         |

The following figure shows the MIPI D-PHY TX IP and MIPI RX IP connected in a system. Config 1 and Config 2 can be in the same or multiple device(s)/board(s).

Figure 26: MIPI D-PHY TX and RX System

X16507-032116

The following figure shows the reset assertion sequence for MIPI D PHY Core:

Figure 27: Reset Assertion Sequence for MIPI D-PHY Core

## Resetting the MIPI D-PHY TX and RX Core

To reset the MIPI D-PHY TX and RX core in a system, perform the following procedure:

1. Assert `core_rst` of MIPI D-PHY TX IP core for minimum 40 `core_clk` cycles.
2. Assert `core_rst` of MIPI D-PHY RX IP core for minimum 40 `core_clk` cycles.
3. Release the MIPI D-PHY RX `core_rst` signal.

**Note:** When there are multiple instances of D-PHY within the same bank, or when there are TX and RX in same bank, perform the reset removal at same time.

4. Release the MIPI D-PHY TX `core_rst` signal.

**Note:** When there are multiple instances of D-PHY within the same bank, or when there are TX and RX in same bank, perform the reset removal at same time.

5. The MIPI D-PHY RX IP core initialization happens after a `T_INIT_SLAVE` time of 100  $\mu$ s and is indicated by the assertion of `stopstate`.
6. The MIPI D-PHY TX IP core initialization happens after a `T_INIT_MASTER` time of 1 ms and is indicated by `stopstate` assertion.
7. At this point, the MIPI D-PHY TX IP core is ready to accept data from the TX PPI interface.

**Note:** The impact of the assertion of `core_rst` on the MIPI D-PHY core is the same as the assertion of the `DPHY_EN` bit of the `CONTROL` register.

### Resetting TX-Only Designs

1. Assert the MIPI D-PHY TX IP `core_rst`.
2. Hold reset signals for a minimum of 40 `core_clk` cycles.
3. Deassert the MIPI D-PHY TX `core_rst` signal.
4. The MIPI D-PHY TX IP core initialization completes after a `T_INIT_MASTER` time of 1 ms and is indicated by the assertion of the `stopstate` signal.
5. At this point, the MIPI D-PHY RX IP core is ready to accept, and the MIPI D-PHY TX IP core is ready to send, data fed from the TX PPI interface.

### Resetting RX-Only Designs

1. Assert the MIPI D-PHY RX IP `core_rst`.
2. Hold the reset signals for a minimum of 40 `core_clk` cycles.
3. Deassert the MIPI D-PHY RX `core_rst` signal.
4. The MIPI D-PHY RX IP core initialization completes after a `T_INIT_SLAVE` time of 100  $\mu$ s. This is indicated by the assertion of the `stopstate` signal.
5. At this point, the MIPI D-PHY RX IP core is ready to accept MIPI D-PHY serial data from the TX partner.

---

## Protocol Description

A high-speed clock is generated from the clock lane and is used for high-speed operations. The line status is detected based on low-power signals. During normal operation, the Lane module is always in the control mode or high-speed mode. High-speed operations happen in bursts, and start from and end in the Stop state (LP-11).

**IMPORTANT!** A low-power line state of less than 20 ns is ignored by the MIPI D-PHY RX core.

The following sections describe the features of the MIPI D-PHY Controller in detail.

### Initialization

After power-up, the slave side PHY is initialized when the master PHY drives a Stop state for a period longer than `T_INIT`. The first Stop state (LP-11) that is longer than the specified `T_INIT` is called the Initialization period.

**Note:** `T_INIT` is considered a protocol-dependent parameter which must be longer than 100  $\mu$ s.

## High Speed Transfer

High-speed signaling is used for fast data traffic. High-speed data communication appears in bursts with an arbitrary number of payload data bytes.

## High Frequency Clock Transmission

The clock lane transmits a low-swing, differential high-speed DDR clock from the master to the slave for high-speed data transmission. It is controlled by the protocol through the clock lane PPI. The clock signal has quadrature-phase with a toggling bit sequence on the data lane.

## Escape Mode

The low-power (LP) functions include single-ended transmitters (LP-TX), receivers (LP-RX), and Low-Power Contention-Detectors (LP-CD). Because this core supports only unidirectional communication, contention detector logic is not required. Low-power functions are always present in pairs as these are single-ended functions operating on each of the two interconnect wires individually.

### *Remote Triggers*

The MIPI D-PHY Controller defines four types of trigger commands. In escape mode, the MIPI D-PHY applies Spaced-One-Hot bit encoding for asynchronous communication. Therefore, operation of a data lane in this mode does not depend on the clock lane. Trigger signaling is the mechanism to send a flag to the protocol at the receiving side, on request of the protocol on the transmitting side. So, data received after the trigger command is not interpreted by the core.

### *Low Power Data Transmission*

Low-Power Data Transmission (LPDT) data can be communicated by the protocol at low speed, while the lane remains in low-power mode. Data is encoded on the lines with the Spaced-One-Hot code. The data is self-clocked by the applied bit encoding and does not rely on the clock lane. The core supports a maximum data transfer of 10 Mb/s in low-power (LP) mode.

**Note:** The maximum clock frequency is 20 MHz in LPDT.

### *Ultra-Low Power State*

This is one type of escape mode and is supported by both the clock lane and data lane. You can exit the ultra low power state by doing the following:

- If the D-PHY RX ULPS WAKEUP counter for 1 ms time option is selected, D-PHY TX must send the Mark-1 (LP-10) state for a duration of 1 ms or longer, then drive the stop-state to make RX exits from the ULPS state.

- If the D-PHY RX ULPS WAKEUP counter for 1ms time option is *not* selected, then D-PHY RX IP checks only for the Mark-1 (LP-10) transition to exit from the ULPS mode.

## Interfaces

The MIPI D-PHY Controller has a PPI interface and an AXI4-Lite interface.

### PPI Interface

The following section explains the PPI timing through a series of examples.

#### Example 1: High-Speed Transmit from D-PHY TX (Master) Side

1. While `txrequesths` is Low, the lane module ignores the value of `txdatahs[7:0]`. To begin transmission, the protocol drives the `txdatahs` signal with the first byte of data and asserts the `txrequesths` signal.
2. This data byte is accepted by the D-PHY on the first rising edge of `txbyteclkhs` with `txreadyhs` also asserted. Now, the protocol logic drives the next data byte onto `txdatahs`. After every rising clock cycle with `txreadyhs` active, the protocol supplies a new valid data byte or ends the transmission.
3. After the last data byte has been transferred to the lane module, `txrequesths` is driven Low to cause the lane module to stop the transmission and enter Stop state.
4. The `txreadyhs` signal is driven Low after `txrequesths` goes Low.

This section describes a high-speed transmission by the D-PHY TX (Master) IP.

The minimum number of bytes transmitted can be as small as one.

**Note:** The `txrequesths` signal of the TX clock lane must be asserted to start the high-speed data transfer.

The following figure shows the high-speed transmission by the D-PHY TX (Master) IP.

**Figure 28: High-Speed Mode Data Transfer from D-PHY TX (Master)**

The start-up time can be calculated using.

$$2 * LPX\_TIME + HS\_PREPARE\_TIME + HS\_ZERO\_TIME + CDC\_DELAY.$$

Where `HS_PREPARE` and `HS_ZERO` are D-PHY protocol timing parameters and maximum values used in the IP. You cannot control the `HS_PREPARE` and `HS_ZERO` values as they are automatically calculated based on the line rate. You can configure LPX using the AMD Vivado™ IP Catalog. `CDC_DELAY` will be  $30 \text{ ns} + 2 \text{ txbyteclkhs}$ .

## Example 2: Low-Power Data Transfer from D-PHY TX (Master) Side

This section describes low-power data transmission operation.

1. For low-power data transmission, the `txclkesc` signal is used. The PPI directs the data lane to enter low-power data transmission escape mode by asserting `txrequestesc` and setting `txlpdtesc` High.
2. The low-power transmit data is transferred on the `txdataEsc[7:0]` when `txvalidesc` and `txreadyesc` are both active at a rising edge of `txclkesc`. The byte is transmitted in the time after the `txdataesc` is accepted by the MIPI D-PHY TX core (`txvalidesc` and `txreadyesc` are High) and therefore the `txclkesc` continues running for some minimum time after the last byte is transmitted.
3. The PPI knows the byte transmission is finished when `txreadyesc` is asserted.
4. After the last byte has been transmitted, the PPI deasserts `txrequestesc` to end the low-power data transmission. This causes `txreadyesc` to return Low, after which the `txclkesc` clock is no longer needed.

The following figure shows the low-power data transmission operation.

Figure 29: Low-Power Data Transfer from D-PHY TX (Master)

## Example 3: Trigger Command Transmission from D-PHY TX (Master) Side

This section describes trigger transmission operation.

1. `txrequestesc` is asserted along with the trigger value in `txtriggeresc[3:0]`.
2. Because the PPI does not have a handshake signal to report back the trigger transmission on the serial line, `txrequestesc` is driven Low after 30 `txclkesc` clock cycles. The 30 clock cycles ensures that the MIPI D-PHY TX core transfers the trigger command on the serial line.

The following figure shows the trigger transmission operation.

Figure 30: Trigger Command Transmission from D-PHY TX (Master)

### Example 4: D-PHY TX (Master) Data Lane ULPS Operation

This section describes a TX data lane ULPS operation.

1. The PPI drives `txrequestesc` High to initiate the ULPS entry request. The `txulpsesc` signal is asserted for one `txclkesc` cycle.
2. The MIPI D-PHY TX core drives the data lane `ulpsactivenot` (active-Low) to Low which indicates that the ULPS command is transmitted on the serial lines.
3. The PPI drives the `txulpsexit` pulse to start the ULPS exit operation.
4. The MIPI D-PHY TX core responds by deasserting the `ulpsactivenot` signal and starts transmitting MARK-1 on the line for `T_WAKEUP` time.
5. The PPI deasserts the `txrequestesc` after `T_WAKEUP` time has elapsed following the deassertion of the `ulpsactivenot` signal.

The following figure shows TX data lane ULPS operation.

Figure 31: D-PHY TX (Master) ULPS Mode Operation for Data Lane

### Example 5: D-PHY TX (Master) Clock Lane ULPS Operation

This section describes a TX clock lane ULPS operation.

1. The PPI drives `txulpsclk` to initiate the clock lane ULPS mode.
2. The MIPI D-PHY TX core drives the clock lane `ulpsactivenot` (active-Low) to Low after the ULPS entry sequence is transmitted on the serial line.
3. The PPI asserts the `txulpsexit` signal to exit from ULPS.

4. The MIPI D-PHY TX core drives the `ulpsactivenot` High and drives MARK-1 on the serial lines.
5. The PPI deasserts the `txrequestesc` after `T_WAKEUP` time has elapsed following deassertion of the `ulpsactivenot` signal.

The following figure shows the TX clock lane ULPS operation.

**Figure 32: D-PHY TX (Master) ULPS Mode Operation for Clock Lane**

### Example 6: High-Speed Receive at D-PHY RX (Slave) Side

This section describes a high-speed reception at the slave side PPI. This behavior is shown in the following figure.

The `rxactivehs` signal indicates that a receive operation is occurring. A normal reception starts with a pulse on `rxsynchs` followed by valid receive data on subsequent cycles of `rxbyteclkhs`. Note that the protocol is prepared to receive all of the data. There is no method for the receiving protocol to pause or slow data reception.

Because end-of-transmission (EoT) processing is not performed in the PHY, one or more additional bytes are presented after the last valid data byte. The first of these additional bytes, shown as byte “C” in the following figure, is either all 1s or all 0s. Subsequent bytes might or might not be present and can have any value. The `rxactivehs` and `rxvalidhs` signals transition Low simultaneously sometime after byte “C” is received. After these signals have transitioned Low, they remain Low until the next high-speed data reception begins.

**Figure 33: High-Speed Mode Data Receive at the D-PHY RX (Slave)**

**Note:** D-PHY RX data lanes operate independently and the received high-speed data, from the serial lines, is passed to the higher layers through PPI. MIPI D-PHY RX IP does not perform any byte alignment or inter-lane skew between RX data lanes. It is the responsibility of the higher layer protocol cores. MIPI CSI-2 Receiver Subsystem compensates up to two `rxbyteclkhs` clock cycles between RX data lanes PPI High-Speed data.

### Example 7: High-Speed Receive with Synchronization Error at D-PHY RX (Slave) Side

The MIPI D-PHY RX core can detect a start-of-transmission (SoT) pattern with single-bit error. It is reported by the assertion of `rxerrs0ths` for one clock cycle of `rxbyteclkhs` along with the `rxsynchs` pulse. This behavior is shown in the following figure.

**Figure 34: High-Speed Mode Data Receive with Synchronization Error at the D-PHY RX (Slave)**

### Example 8: High-Speed Mode Data Receive with Loss of Synchronization at D-PHY RX (Slave) Side

The MIPI D-PHY RX core reports the multi-bit error on the SoT pattern by asserting `rxerrs0tsynchs` for one clock cycle of `rxbyteclkhs`. This scenario indicates that the SoT pattern is corrupted. Note that `rxsynchs` is not asserted. Received payload is passed on to the PPI. This behavior is shown in the following figure.

**Figure 35: High-Speed Mode Data Receive with Loss of Synchronization at the D-PHY RX (Slave)**

### Example 9: Low-Power Receive at D-PHY RX (Slave) Side

The following figure shows a single-byte data reception in low-power mode.

- The `rxclkesc` signal is generated by the MIPI D-PHY RX core from the data lane interconnect.
- The signal `rxlpdtesc` is asserted by the MIPI D-PHY RX core when the LPDT entry command is detected and stays High until the data lane returns to the Stop state, indicating that the LPDT transmission has finished.
- `rxdataesc[7:0]` is valid when `rxvalidesc` is asserted High.

**Figure 36: Low-Power Data Reception at the D-PHY RX (Slave)**

### Example 10: Low-Power Data Receive with Synchronization Error at D-PHY RX (Slave) Side

The MIPI D-PHY RX core reports an error to the PPI if the number of received valid bits during LPDT is not a multiple of eight. This is indicated by asserting `errsyncesc` along with `stopstate` and remains asserted until the next change in the serial line state. This behavior is shown in the following figure.

**Figure 37: Low-Power Data Reception with Synchronization Error at the D-PHY RX (Slave)**

### Example 11: ULPS Operation at D-PHY RX (Slave) Data Lane

The RX Data lane ULPS entry is indicated by assertion of `rxulpsesc` along with assertion of `ulpsactivenot` (active-Low) signal. ULPS exit is marked by reception of MARK-1 on the line and `ulpsactivenot` is deasserted. After receiving MARK-1 for `T_WAKEUP` time (1 ms minimum), `rxulpsesc` is deasserted. This behavior is shown in the following figure.

**Figure 38: D-PHY RX (Slave) ULPS Mode Operation for Data Lane**

### Example 12: ULPS Operation at D-PHY RX (Slave) Clock Lane

The RX clock lane ULPS entry is indicated by assertion of `rxulpsclknot` (active-Low) along with assertion of `ulpsactivenot` (active-Low) signal. ULPS exit is marked by reception of MARK-1 on the line and `ulpsactivenot` is deasserted. After receiving MARK-1 for `T_WAKEUP` time (1 ms minimum), `rxulpsclknot` is deasserted. This behavior is shown in the following figure.

Figure 39: D-PHY RX (Slave) ULPS Mode Operation for Clock Lane

### Example 13: RX Data Lane Initialization Using `forcerxmode`

The RX data lane can be initialized using the `forcerxmode` signal. This behavior is shown in the following figure.

1. `forcerxmode` is the asynchronous signal and is sampled using `core_clk`.
2. The `forcerxmode` assertion resets the lane initialization status, which is shown as the `init_done` signal in the waveform.
3. LP-11 should be driven on dp/dn serial lines for `T_INIT` or longer by the MIPI D-PHY TX (Master). This initializes the RX data lane.
4. `stopstate` is driven High after lane is initialized.
5. `forcerxmode` can be deasserted by sampling `stopstate`.

Figure 40: RX Data Lane Initialization Using `forcerxmode`

**Note:** Back channel communication is not available from the MIPI D-PHY RX (Slave) to the MIPI D-PHY TX (Master). Hence, you are responsible for making sure that MIPI D-PHY TX drives LP-11 on serial lines after `forcerxmode` is asserted on the MIPI D-PHY RX core module. Otherwise, the MIPI D-PHY RX core does not complete the initialization.

## AXI4-Lite Interface

The register interface uses an AXI4-Lite interface, which was selected because of its simplicity. The following figures show typical AXI4-Lite write and read transaction timings.

Figure 41: AXI4-Lite Write Timing Diagram

Figure 42: AXI4-Lite Read Timing Diagram

# Design Flow Steps

This section describes customizing and generating the core, constraining the core, and the simulation, synthesis, and implementation steps that are specific to this IP core. More detailed information about the standard AMD Vivado™ design flows and the IP integrator can be found in the following Vivado Design Suite user guides:

- *Vivado Design Suite User Guide: Designing IP Subsystems using IP Integrator* ([UG994](#))
- *Vivado Design Suite User Guide: Designing with IP* ([UG896](#))
- *Vivado Design Suite User Guide: Getting Started* ([UG910](#))
- *Vivado Design Suite User Guide: Logic Simulation* ([UG900](#))

---

## Customizing and Generating the Core

This section includes information about using AMD tools to customize and generate the core in the AMD Vivado™ Design Suite.

If you are customizing and generating the core in the Vivado IP integrator, see the *Vivado Design Suite User Guide: Designing IP Subsystems using IP Integrator* ([UG994](#)) for detailed information. IP integrator might auto-compute certain configuration values when validating or generating the design. To check whether the values do change, see the description of the parameter in this chapter. To view the parameter value, run the `validate_bd_design` command in the Tcl console.

You can customize the IP for use in your design by specifying values for the various parameters associated with the IP core using the following steps:

1. Select the IP from the IP catalog.
2. Double-click the selected IP or select the Customize IP command from the toolbar or right-click menu.

For details, see the *Vivado Design Suite User Guide: Designing with IP* ([UG896](#)) and the *Vivado Design Suite User Guide: Getting Started* ([UG910](#)).

Figures in this chapter are illustrations of the Vivado IDE. The layout depicted here might vary from the current version.

## Core Configuration Tab

The following figure shows the Core Configuration tab for customizing the MIPI D-PHY Controller.

Figure 43: Core Configuration Tab for D-PHY TX

Figure 44: Core Configuration Tab for D-PHY RX

## Component Name

The Component Name is the base name of the output files generated for this core.

**IMPORTANT!** The name must begin with a letter and be composed of the following characters: a to z, A to Z, 0 to 9 and "\_".

## Core Parameters

- **D-PHY Lanes:** Select the number of data lanes to be used in the core. The valid range for TX is from 1 to 4, and for RX is from 1 to 8.
- **Line Rate:** Enter a line rate value in megabits per second (Mb/s) within the valid range: 80 to 3200 Mb/s based on the device selected. The Vivado IDE automatically limits the line rates based on the device selected. For details about family/device specific line rate support, refer to the respective device data sheet. For example:

Table 33: MIPI D-PHY Performance Zynq UltraScale+ MPSoC

| Description                                                    | I/O Bank Type | Conditions <sup>1</sup>                                         | Speed Grade and V <sub>CCINT</sub> Operating Voltages |       |                   |       |      | Units |
|----------------------------------------------------------------|---------------|-----------------------------------------------------------------|-------------------------------------------------------|-------|-------------------|-------|------|-------|
|                                                                |               |                                                                 | 0.90V                                                 | 0.85V |                   | 0.72V |      |       |
|                                                                |               |                                                                 | -3                                                    | -2    | -1                | -2    | -1   |       |
| Maximum MIPI D-PHY transmitter or receiver data rate per lane. | HP            | XC and XA devices using Vivado tools 2019.2.2 or later.         | 2500                                                  | 2500  | 2500 <sup>2</sup> | 2500  | 1260 | Mb/s  |
|                                                                |               | XC and XA devices using Vivado tools 2019.1.1 through 2019.2.1. | 2500                                                  | 2500  | 1260              | 2500  | 1260 | Mb/s  |
|                                                                |               | XC and XA devices using Vivado tools 2019.1 or earlier.         | 1500                                                  | 1500  | 1260              | 1260  | 1260 | Mb/s  |
|                                                                |               | XQ devices                                                      | 1500                                                  | 1500  | 1260              | 1260  | 1260 | Mb/s  |
|                                                                |               | All devices in SBVA484, SFRA484, UBVA494, and UBVA530 packages. | 1260                                                  | 1260  | 1260              | 1260  | 1260 | Mb/s  |

**Notes:**

- For applicable conditions, the lower maximum data rate applies.
- XA devices with the -1Q speed grade require Vivado tools 2020.1, or later, for data rates greater than 1260 Mb/s.
- Refer to *Zynq UltraScale+ MPSoC Data Sheet: DC and AC Switching Characteristics* ([DS925](#)) for latest updates.

- Data Flow:** Select the options for the direction of the data transfer. Available options are TX (for Master) and RX (for Slave).
- Enable Splitter Bridge Mode:** Select this to enable splitter bridge mode. This allows replication of the received MIPI camera stream to multiple (1 to 4) MIPI output streams for further processing by external modules.
- Number of TX Interfaces:** Select the number MIPI output TX interfaces when Enable Splitter Bridge Mode is selected. You can select up to four TX interfaces. Based on number of TX interfaces selected, the GUI allows I/O configuration for all these interfaces separately. I/Os of each TX interface can be in the same bank or a different bank.

**Note:** Ensure all TX I/Os are exclusive and follow IO guidelines.

- Escape Clk (MHz):** Enter a valid escape clock frequency in MHz into the text box for the MIPI D-PHY Master (TX) core. The valid range is from 10.000 to 20.000 MHz. Applicable only for the MIPI D-PHY TX core.
- LPX Period (ns):** Enter a valid LPX Period in nanoseconds (ns) into the text box for MIPI D-PHY Master (TX) core. The valid range is from 50 to 100 ns.

- **D-PHY RX ULPS WAKEUP counter for 1 ms time:** Select the option to include 1 ms WAKEUP counter. Otherwise, D-PHY RX IP checks only for the LP-10 transition to exit from the ULPS mode.

**Note:** Available only for D-PHY RX configurations.

- **Resource Optimization presets:** By using the mentioned presets, you can reduce the resources depending upon the requirements.

If preset `CSI2RX_XLNX` is selected, the ULPS and LPDT features are not supported by the core.

If preset `CSI2RX_XLNX2` is selected, the ULPS and LPDT features, `errorsotsynchs` assertion, and the checking of the LPX period are not supported by the core.

If preset `CSI2TX_XLNX` is selected, the ULPS and ESC features are not supported by the core; furthermore, the register interface is removed, and the clock and data lane status information is provided through ports.

- **IDELAY\_GROUP Name:** This parameter is used to select the IDELAY\_GROUP name for the IDELAYCTRL. All core instances in the same bank sharing IDELAYCTRL should have the same name for this parameter. Select a unique name per bank.

**Note:** Available only for 7 series D-PHY RX configurations.

- **Enable deskew sequence detection logic:** This parameter is used to enable the deskew detection logic. When a deskew packet is received, D-PHY does the eye centering between clock and data.

**Note:** The minimum required length of the periodic calibration pattern is  $2^{13}$  UI.

**Note:** When this feature is selected, then the maximum supported lanes is 4.

- **Enable the SSC Clock:** This parameter is used when the SSC feature is required. When this parameter is selected, you must drive the SSC-enabled byte clock (`ssc_byteclkhs_in`) to the core when the line rate is greater than 2500 Mb/s and when the shared logic is inside the core.
- **Transmit First Deskew Calibration Sequence:** This parameter is used to enable the initial deskew pattern in D-PHY TX configuration.
- **T\_SKEWCAL Parameter for first deskew seq (txbyteclkhs clocks):** This parameter defines the length of the initial calibration sequence.
- **Transmit Periodic deskew calibration sequence:** This parameter is used to enable the periodic deskew pattern in D-PHY TX configuration.

**Note:** The length of the periodic pattern depends on the length of `dl<n>-txskewcalhs`.

- **Line rate supported by device Data sheet:** This option is available only for 7 series devices. Select this option if the line rate is within the range of the selected device. Else, refer to the data sheet for line rate limitations.
- **Guarantees the clock Rising Edge Alignment to first payload bit on serial lines:** This option is available for AMD Versal™ adaptive SoC TX configuration. When selected, the first payload bit is aligned to rising edge of the serial clock.

When the option 'Guarantees the clock Rising Edge Alignment to first payload bit on serial lines' is enabled, the first payload bit is aligned to the rising edge if the parameter is disabled. Then the first payload bit cannot be guaranteed to be on the rising edge of the clock.

**Figure 45: Option Enabled: Guarantees the lock Rising Edge Alignment to first payload bit on serial lines**

## Control and Debug

- **Infer OBUFTDS for 7 series HS outputs:** Select this option to infer OBUFTDS for HS outputs.

**Note:** This option is available only for 7 series D-PHY TX configurations. It is recommended to use this option for D-PHY compatible solution based on resistive circuit. For details, see *D-PHY Solutions* ([XAPP894](#)).

- **Enable Active Lane support:** Select this option to control TX data lanes. Active lanes allows the D-PHY TX to run with lower lanes than IP is configured for. This helps the lane down scaling and disabling any TX data lane by the deasserting corresponding bit in the `active_lanes_in` bus input. It is recommended to update the `active_lanes_in` when all data lanes are in stopstate. HS\_TX\_TIMEOUT is disabled internally when the `active_lanes_in` feature is exercised. Lane 0 is always enabled (otherwise, `txreadyhs` is not asserted).
- **Enable AXI4-Lite Register I/F:** Select the AXI4-Lite-based register interface for control and debug purposes.

## Protocol Watchdog Timers

- **Enable HS and ESC Timeout Counters/Registers:** Enable the HS\_TX\_TIMEOUT/HS\_RX\_TIMEOUT and ESC\_TIMEOUT counters. Select this option to enable the HS\_TIMEOUT and ESC\_TIMEOUT registers provided that the AXI4-Lite register interface is enabled.
- **HS Timeout (Bytes):** Enter the maximum transmission or reception length in bytes for High-Speed mode. The valid range is from 1,000 to 65,541 bytes.

- **Escape Timeout (ns):** Enter the maximum transmission or reception length in ns for LPDT escape mode. The valid range is from 800 to 25,600 ns.
- **Calibration Mode:** Select the calibration for 7 series D-PHY RX IP. Available options:
  - None (default selection) - Does not add IDELAYE2 primitive.
  - Fixed - Sets the IDELAYE2 TAP value given in the IDELAY Tap Value.
  - Auto - Adds the IDELAYE2 primitive. IDELAY Tap Value will be configured by D-PHY RX IP based on received traffic and calibration algorithm. IP uses the DIFF\_TERM=TRUE setting for input buffers when Calibration mode is set to Auto. Auto algorithm performs a skew calibration on the runtime. It usually requires HS packet reception by D-PHY RX IP to determine the correct IDELAY tap value. This mode is available for line rates above 450 Mb/s.

- **External IDELAY tap loading:** Allows to load IDELAY tap values through external ports in "Fixed" mode of Calibration.

**Note:** It is recommended to clock these ports through core\_clk.

- **IDELAY Tap Value:** Enter IDELAY TAP value used calibration in fixed mode. The valid range is from 1 (default option) to 31.
- **Include IDELAYCTRL in core:** For multiple D-PHY RX IP cores that are sharing single IO bank, select this option to include IDELAYCTRL in the IP for the auto calibration mode. Only one IDELAYCTRL is available per I/O bank. In case of multiple D-PHY RX cores in single I/O bank, only one D-PHY RX IP core should have this option selected. For the rest of D-PHY RX cores, this option should be unselected.

**Note:** This option is applicable only for 7 series D-PHY RX IP configurations.

- **Enable 300 MHz clock for IDELAYCTRL:** Select this option to connect 300 MHz to IDELAYCTRL and is used in auto calibration mode.

**Note:**

- This option is applicable only for 7 series D-PHY RX IP configuration.
- For 7 series in AUTO Mode, when there are multiple instances of DPHY and they share the IDELAY control ready from one DPHY instance to other DPHY instance. The DPHY instance which shares the IDELAY controller ready cannot have the Enable 300 MHz clock for IDELAYCTRL parameter set to true.
- For 7 series, internal IP timing is tested and validated to a maximum of 1250 Mb/s. Meeting timing at Line Rates Higher than 1250 Mb/s might be possible depending on setup and are available in the GUI.

**Note:** Internal timing limitations are different than physical timing limitations, which are based on the PCB configuration and might be lower. The variables are the use of an external PHY, resistor network and termination options. Validate that the full system can handle the line rate requirement of your design. See *D-PHY Solutions* ([XAPP894](#)) for more information.

## Shared Logic Tab

The following figure shows the Shared Logic tab of the Customize IP interface.

**Note:** This tab is not available for 7 series D-PHY RX configurations.

Figure 46: Shared Logic Tab

This tab allows you to select whether the MMCM and PLL are included in the core or in the example design. Following are the available options:

- Include Shared Logic in core
- Include Shared Logic in example design (default selection)
- MMCM Sharing Across the banks is available if you select Include Shared Logic in the core.

## Pin Assignment Tab

The following figure shows the I/O pin parameters for the core. For more information on the optimal IO pin assignment, see [Appendix C, Pin and Bank Rules](#).

**Note:** This tab is not available for 7 series and Versal D-PHY RX configurations.

Figure 47: Pin Assignment Tab

- **HP IO Bank Selection:** Select the HP I/O bank for clock lane and data lane implementation.

**Note:** This option is not available for 7 series FPGAs as D-PHY can be implemented in both HR bank IO and HP bank IO.

- **Clock Lane:** Select the LOC for the clock lane. This selection determines the I/O byte group within the selected HP I/O bank.
- **Data Lane 0/1/2/3:** This displays the Data lane 0, 1, 2, and 3 LOC based on the clock lane selection.

## User Parameters

The following table shows the relationship between the fields in the AMD Vivado™ IDE and the user parameters (which can be viewed in the Tcl Console).

Table 34: Vivado IDE Parameter to User Parameter Relationship

| Vivado IDE Parameter/Value                                           | User Parameter/Value | Default Value        |
|----------------------------------------------------------------------|----------------------|----------------------|
| <b>Core Parameters</b>                                               |                      |                      |
| D-PHY Lanes                                                          | C_DPHY_LANES         | 1                    |
| Line Rate (Mb/s)                                                     | C_LINE_RATE          | 1,000                |
| Data Flow Mode                                                       | C_DATA_FLOW          | Master (TX)          |
| Escape Clk (MHz)                                                     | C_ESC_CLK_PERIOD     | 20.000               |
| LPX (ns)                                                             | C_LPX_PERIOD         | 50                   |
| D-PHY RX ULPS WAKEUP counter for 1 ms time                           | C_EN_ULPS_WAKEUP_CNT | False                |
| IDELAY_GROUP name                                                    | C_IDLY_GROUP_NAME    | mipi_dphy_idly_group |
| Enable the SSC clock                                                 | C_EN_SSC             | False                |
| Guarantees the rising edge clock alignment to first payload data bit | C_EN_DCTS_LOGIC      | False                |
| External IDELAY tap loading                                          | C_EN_EXT_TAP         | False                |
| <b>Protocol Watchdog Timers</b>                                      |                      |                      |
| Enable Deskew Sequence detection Logic                               | C_RCVE_DESKEW        | 0                    |
| Enable HS and ESC timeout counters/ Registers                        | C_EN_TIMEOUT_REGS    | 0                    |
| HS Timeout (Bytes)                                                   | C_HS_TIMEOUT         | 65,541               |
| Escape Timeout (ns)                                                  | C_ESC_TIMEOUT        | 25,600               |
| <b>Debug and Control</b>                                             |                      |                      |
| Enable Register Interface                                            | C_EN_REGIF           | 0                    |
| OBUFTDS Inference                                                    | C_EN_HS_OBUFTDS      | 0                    |
| Active Lane Support                                                  | C_EN_ACT_LANES       | 0                    |
| HS_SETTLE Parameter (ns)                                             | C_HS_SETTLE_NS       | 145                  |
| Internal MMCM                                                        | C_EXT_MMCM           | 0                    |
| External MMCM                                                        | C_EXT_MMCM           | 1                    |

## Output Generation

For details, see the *Vivado Design Suite User Guide: Designing with IP* ([UG896](#)).

## Constraining the Core

### Required Constraints

This section defines the additional constraint requirements for the core. Constraints are provided with a Design Constraints (XDC) file. An XDC is provided with the HDL example design to give a starting point for constraints for your design.

## Device, Package, and Speed Grade Selections

Select the device, package and speed grades after referring to the following data sheets for details on supported maximum data rate supported.

- *Kintex UltraScale+ FPGAs Data Sheet: DC and AC Switching Characteristics* ([DS922](#))
- *Virtex UltraScale+ FPGA Data Sheet: DC and AC Switching Characteristics* ([DS923](#))
- *Zynq UltraScale+ MPSoC Data Sheet: DC and AC Switching Characteristics* ([DS925](#))
- *Artix UltraScale+ FPGA Data Sheet: DC and AC Switching Characteristics* ([DS931](#))
- *Versal AI Core Series Data Sheet: DC and AC Switching Characteristics* ([DS957](#))

## Clock Frequencies

`core_clk` should be specified as follows:

```
create_clock -name core_clk -period 5.000 [get_ports core_clk]
```

This constraint defines the frequency of `core_clk` that is supplied to the MMCM and PCS logic.

## Clock Management

The MIPI D-PHY Controller uses an MMCM to generate the general interconnect clocks, and the PLL is used to generate the serial clock and parallel clocks for the PHY. The input to the MMCM is constrained as shown in Clock Frequencies. No additional constraints are required for the clock management.

## Clock Placement

This section is not applicable for this IP core.

## Banking

The MIPI D-PHY Controller provides the Pin Assignment Tab option to select the HP I/O bank. The clock lane and data lane(s) are implemented on the selected I/O bank BITSlice(s). When placing multiple cores, please follow banking rules for the target architecture. For AMD UltraScale™, refer to *UltraScale Architecture SelectIO Resources User Guide* ([UG571](#)), and for Versal, refer to *Versal Adaptive SoC SelectIO Resources Architecture Manual* ([AM010](#)) for more details.

**Note:** Pin assignment is not applicable for 7 series FPGAs and Versal DPHY IP configurations.

## Transceiver Placement

This section is not applicable for this IP core.

## I/O Standard and Placement

MIPI standard serial I/O ports should use MIPI\_DPHY\_DCI for the I/O standard in the XDC file for AMD UltraScale+™ families. The LOC and I/O standards must be specified in the XDC file for all input and output ports of the design. UltraScale+ MIPI D-PHY IP generates the IO pin LOC for the pins that are selected during IP customization. No IO pin LOC are provided for 7 series MIPI D-PHY IP designs. You have to manually select the clock capable IO for 7 series RX clock lane and restrict the IO selection within the IO bank for both D-PHY TX and D-PHY RX IP configurations.

It is recommended to select the IO bank with `VRP` pin connected for UltraScale+ MIPI D-PHY TX/RX IP core. If `VRP` pin is present in other IO bank in the same IO column of the device, the following DCI\_CASCADE XDC constraint should be used. For example, IO bank 65 has a `VRP` pin and the D-PHY TX IP is using the IO bank 66.

```
set_property DCI_CASCADE {66} [get_iobanks 65]
```

For more information on MIPI\_DPHY\_DCI IO standard and `VRP` pin requirements, see the *UltraScale Architecture SelectIO Resources User Guide* ([UG571](#)).

---

## Simulation

For comprehensive information about AMD Vivado™ simulation components, as well as information about using supported third-party tools, see the *Vivado Design Suite User Guide: Logic Simulation* ([UG900](#)).

---

## Synthesis and Implementation

For details about synthesis and implementation, see the *Vivado Design Suite User Guide: Designing with IP* ([UG896](#)).

# Example Design

This chapter contains information about the example design provided in the AMD Vivado™ Design Suite.

## Overview

The top module instantiates all components of the core and example design that are needed to implement the design in hardware, as shown in the following figure. This includes the FRM\_GEN, DPHY TX IP, FRM\_CHK, and the DPHY RX IP modules.

Figure 48: MIPI D-PHY Core Example Design

X23419-102319

The FRM\_GEN module generates user traffic for High-Speed mode and low-power data transmission (LPDT). This module contains a pseudo-random number generator using a linear feedback shift register (LFSR) with a specific initial value to generate a predictable sequence of data.

The FRM\_CHK module verifies the integrity of the RX data. This module uses the same LFSR and initial value as the FRM\_GEN module to generate the expected RX data. The received user data is compared with the locally-generated data and an error is reported if data comparison fails. The example design can be used to quickly get a MIPI D-PHY Controller design up and running on a board, or perform a quick simulation of the module. When using the example design on a board, be sure to edit the `<component name>_exdes.xdc` file to supply the correct pins and clock constraints.

**IMPORTANT!** *This implementation is used only for reference and as a demonstration of the example test bench.*

Implementing the AMD Versal™ Example Design:

1. When the Example design is open, synthesize the ex-design.
2. When synthesis is done, open the synthesized design & execute the following command in Tcl console 'xphy::generate\_constraints'.
3. Save the `xdc` and implement the design.

## Simulating the Example Design

For more information about simulation, see the *Vivado Design Suite User Guide: Logic Simulation (UG900)*.

The simulation script performs the following:

1. Compiles the MIPI D-PHY example design and supporting simulation files.
2. Runs the simulation.
3. Runs checks to ensure that it completed successfully.

If the test passes, the following message is displayed:

```
MIPI_D-PHY_TB : INFO: Test Completed Successfully
```

If the test fails, the following message is displayed:

```
MIPI_D-PHY_TB : ERROR: Test Failed
```

If the test hangs, the following message is displayed:

```
MIPI_D-PHY_TB : ERROR: Test did not complete (timed-out)
```

# Test Bench

This chapter contains information about the example design provided in the AMD Vivado™ Design Suite.

The MIPI D-PHY Controller delivers a demonstration test bench for the example design. This chapter describes the MIPI D-PHY Controller test bench and its functionality. The test bench consists of the following modules:

- Device Under Test (DUT)
- Clock and reset generator
- Status monitor

The example design demonstration test bench is a simple Verilog module to exercise the example design and the core itself. It simulates an instance of the MIPI D-PHY TX example design that is externally looped back to the MIPI D-PHY RX example design. The following figure shows the MIPI D-PHY Controller test bench where `DUT1` is configured as `D-PHY TX`, and `DUT2` is configured as `D-PHY RX`.

The MIPI D-PHY Controller test bench generates all the required clocks and resets, and waits for successful data pattern checking to complete. If it fails to detect successful data pattern checking, it produces an error.

**Note:** Example design for AMD Versal™ adaptive SoC is supported only when the example design is in the core.

Figure 49: MIPI D-PHY Test Bench

# Verification, Compliance, and Interoperability

The MIPI D-PHY Controller has been verified using both simulation and hardware testing. A highly parameterizable transaction-based simulation test suite has been used to verify the core. The tests include:

- High-Speed data transmission
- High-Speed data reception
- Low-Power data transmission (LPDT)
- LPDT data reception
- Clock lane Ultra-Low Power State (ULPS) operation
- Data lane ULPS operation
- Triggers and escape mode commands
- Recovery from error conditions
- Register read and write access

---

## Hardware Validation

The MIPI D-PHY Controller is tested in hardware for functionality, performance, and reliability using AMD evaluation platforms. The MIPI D-PHY Controller verification test suites for all possible modules are continuously being updated to increase test coverage across the range of possible parameters for each individual module.

A series of MIPI D-PHY Controller test scenarios are validated using the AMD Zynq™ UltraScale+™ MPSoC ZCU102 development board. This board allows the prototyping of system designs where the MIPI D-PHY Controller is used for high-speed serial communication between two boards.

7 series FPGAs do not have native MIPI IOB support: target the HP/HR IO bank for 7 series FPGAs and the XPIO bank for AMD Versal™ devices.

For more information, refer to *D-PHY Solutions* ([XAPP894](#)).

A series of interoperability test scenarios are listed in the following table that are validated using different core configurations and resolutions.

**Table 35: MIPI CSI2 Sensor Interoperability Testing**

| Sensor             | Board/Device                    | Tested Configuration                            | Resolution                                           |
|--------------------|---------------------------------|-------------------------------------------------|------------------------------------------------------|
| Omnivision OV13850 | ZCU102/xczu9eg-ffvb1156-2-i-es2 | D-PHY RX<br>1200 Mb/s<br>1, 2, 4 Lanes          | 480p@60 fps, 720p@60 fps,<br>1080p@60 fps, 4k@30 fps |

# Debugging

This appendix includes details about resources available on the Support website and debugging tools.

---

## Finding Help with AMD Adaptive Computing Solutions

To help in the design and debug process when using the core, the [Support web page](#) contains key resources such as product documentation, release notes, answer records, information about known issues, and links for obtaining further product support. The [Community Forums](#) are also available where members can learn, participate, share, and ask questions about AMD Adaptive Computing solutions.

### Documentation

This product guide is the main document associated with the core. This guide, along with documentation related to all products that aid in the design process, can be found on the [AMD Adaptive Support web page](#) or by using the AMD Adaptive Computing Documentation Navigator. Download the Documentation Navigator from the [Downloads page](#). For more information about this tool and the features available, open the online help after installation.

### Answer Records

Answer Records include information about commonly encountered problems, helpful information on how to resolve these problems, and any known issues with an AMD Adaptive Computing product. Answer Records are created and maintained daily to ensure that users have access to the most accurate information available.

Answer Records for this core can be located by using the Search Support box on the main [AMD Adaptive Support web page](#). To maximize your search results, use keywords such as:

- Product name
- Tool message(s)

- Summary of the issue encountered

A filter search is available after results are returned to further target the results.

### ***Master Answer Record for the Core***

AR [54550](#).

## **Technical Support**

AMD Adaptive Computing provides technical support on the [Community Forums](#) for this AMD LogiCORE™ IP product when used as described in the product documentation. AMD Adaptive Computing cannot guarantee timing, functionality, or support if you do any of the following:

- Implement the solution in devices that are not defined in the documentation.
- Customize the solution beyond that allowed in the product documentation.
- Change any section of the design labeled DO NOT MODIFY.

To ask questions, navigate to the [Community Forums](#).

---

## **Debug Tools**

There are many tools available to address MIPI D-PHY v4.3 design issues. It is important to know which tools are useful for debugging various situations.

### **Vivado Design Suite Debug Feature**

The AMD Vivado™ Design Suite debug feature inserts logic analyzer and virtual I/O cores directly into your design. The debug feature also allows you to set trigger conditions to capture application and integrated block port signals in hardware. Captured signals can then be analyzed. This feature in the Vivado IDE is used for logic debugging and validation of a design running in AMD devices.

The Vivado logic analyzer is used to interact with the logic debug LogiCORE IP cores, including:

- ILA 2.0 (and later versions)
- VIO 2.0 (and later versions)

See the *Vivado Design Suite User Guide: Programming and Debugging* ([UG908](#)).

# Simulation Debug

The simulation debug flow for Mentor Graphics Questa Advanced Simulator is illustrated in the following figure. A similar approach can be used with other simulators.

Figure 50: Questa Advanced Simulator Debug Flow

X14842-012616

# Hardware Debug

Hardware issues can range from link bring-up to problems seen after hours of testing. This section provides debug steps for common issues. The AMD Vivado™ debug feature is a valuable resource to use in hardware debug. The signal names mentioned in the following individual sections can be probed using the debug feature for debugging the specific problems.

The following figure shows the steps to perform a hardware debug.

*Figure 51: Debug Flow Chart*

X16509-062320

## General Checks

- Ensure that all the timing constraints for the core were properly incorporated from the example design and that all constraints were met during implementation.
- Ensure that MMCM and PLL have obtained lock by monitoring `mmcm_lock_out` and `pll_lock_out` ports respectively.
- Verify the IO pin planning and XDC constraints.
- Follow recommended reset sequence.
- Verify all clocks are connected and are with expected frequencies.

- Enable AXI4-Lite based register interface to get core status and control.
- Make sure serial line trace lengths are equal. For PCB Guidelines refer *UltraScale Architecture PCB Design User Guide* ([UG583](#)).
- Verify the FMC\_VADJ voltage to 1.2V in case of FMC card usage.

## D-PHY Protocol Checks

- Ensure that `HS` and `Escape` transactions are initiated when the core is in `StopState`.
- Check the enable from PPI is connected and it is active-High during operation.
- Ensure bytes transferred or received are within `HS_TIMEOUT` in the case of `HS` mode, and `ESC_TIMEOUT` in the case of `LPDT`.
- Ensure `HS_SETTLE` of D-PHY RX matches with the DPHY specification limits.
- Check received LP transactions are of at least 20 ns duration.
- Monitor PPI error signals such as `errsoths` and `errsotsynchs`. Excessive `errsotsynchs` indicates either `HS_SETTLE` parameter tuning or signal integrity issues on the D-PHY RX link.
- Ensure that there is no skew between different D-PHY RX lanes within same MIPI D-PHY interface. D-PHY RX IP does not perform any inter-lane skew adjustment operations on the received high-speed data. This is left to a higher level protocol layer such as CSI-2 RX.

## Lane Initialization

After the assertion of power-on reset, MMCM lock followed by PLL lock should be asserted by the core. Monitor the `mmcm_lock_out` and `pll_lock_out` signals for the lock status. The serial lines of clock lane and data lane(s) should be driven with LP-11 for a period of `T_INIT`. The `T_INIT` value of the D-PHY RX should be 50% to 80% of the `T_INIT` value of the D-PHY TX. Bit 3 of the `CL_STATUS` or `DL_STATUS` registers confirm the completion of initialization. When the D-PHY core completes the initialization, `stopstate` is asserted on the PPI. Bit 4 of the `CL_STATUS` register and bit 6 of the `DL_STATUS` register indicate the Stop state.

## HS Clock Transfer

The high-speed clock is transmitted on the D-PHY TX clock lane. The assertion of `txrequesths` on the TX clock lane starts the clock transmission. A value of `2'b01` in the `MODE` field of the `CL_STATUS` register confirms the HS clock transfer. The `cl_rxcclkactivehs` PPI signal also can be used to confirm the HS clock reception in the D-PHY RX.

## HS Data Transfer

HS data can be transferred as soon as the HS clock transmission has started. The `txrequesths` signal on the TX data lane starts the data transfer. A value of `2'b01` in the `MODE` field of the `DL_STATUS` register confirms that the data lane is in HS mode. The `PKT_CNT` field of the `DL_STATUS` register provides the numbers of packets transmitted or received by the data lane. The HS mode PPI signals can also be used to monitor the HS data transfer. Each `txrequesths` is counted as one packet in the D-PHY TX and each `rxactivehs` with a `rxsynchs` pulse is considered as one packet in the D-PHY RX. Note that the D-PHY RX also counts erroneous transactions such as `errs0ths` and `errs0tsynchs`.

You can start with a small number of packets from the D-PHY TX and check whether the `PKT_CNT` of both the D-PHY TX and D-PHY RX match. Ensure that all of the control mode sequences are captured without any errors and that the `errcontrol` signal of the PPI RX is asserted if any erroneous control sequence is received on the serial lines. The `HS_ABORT` field in the `DL_STATUS` register is asserted if the D-PHY RX is receiving more bytes than the `HS_TIMEOUT` programmed value.

Monitor `errs0ths` and `errs0tsynchs` and tune the `HS_SETTLE` of D-PHY RX IP after making sure that there are no signal integrity issues. `HS_SETTLE` of D-PHY RX can be changed through AXI4-Lite register interface and user can set desired value of `HS_SETTLE` during IP generation using `HS_SETTLE_NS` hidden user parameter.

---

## AXI4-Lite Interface Debug

Read from a register that does not have all 0s as a default to verify that the interface is functional. Output `s_axi_arready` asserts when the read address is valid, and output `s_axi_rvalid` asserts when the read data/response is valid. If the interface is unresponsive, ensure that the following conditions are met:

- The `s_axi_aclk` and `aclk` inputs are connected and toggling.
- The interface is not being held in reset, and `s_axi_areset` is an active-Low reset.
- The interface is enabled, and `s_axi_aclken` is active-High (if used).
- The main core clocks are toggling and that the enables are also asserted.
- If the simulation has been run, verify in simulation and/or a Vivado Design Suite debug feature captures that the waveform is correct for accessing the AXI4-Lite interface.

# Pin and Bank Rules

This appendix provides guidelines and recommendations to implement multiple D-PHY interfaces on supported AMD devices.

For more information on pin and bank rules, see the *Advanced I/O Wizard LogiCORE IP Product Guide* ([PG320](#)).

**IMPORTANT!** Pin swap functionality between P/N is not supported for any DPHY Lane.

## Pin and Bank Rules for Versal Adaptive SoCs

This section describes the pin rules for AMD Versal™ adaptive SoCs.

- Select any XPIO Bank.
- RX clock lane pins must be "XCC", "GC/XCC" pins.
- Non-continuous IO usage is allowed for D-PHY TX and RX interfaces but not recommended.
- While Selecting the data lane pins for RX it should follow the inter-nibble and inter-byte clocking rules.

**Note:** Refer to [I/O Planning for Versal Devices](#) for detailed pin rules for TX and RX.

## Pin Rules for Zynq UltraScale+ MPSoC Devices

This section describes the pin rules for AMD Zynq™ UltraScale+™ MPSoC devices.

- Clock lane pins are represented with `clk_<>` and data lane pins are represented with `data_<>`.
- D-PHY Interface are numbered from if0 to if7.
- Byte lanes in a bank are designed by T0, T1, T2, or T3. Nibbles within a byte lane are distinguished by a "U" or "L" designator added to the byte lane designator (T0, T1, T2, or T3). Thus, they are T0L, T0U, T1L, T1U, T2L, T2U, T3L, and T3U.
- Pins in a byte lane are numbered from 0 to 12.

**Note:** There are two PLLs per bank and a D-PHY uses one PLL in every bank that is being used by the interface.

## D-PHY RX Pin Rules

- RX clock lane pins must be DBC, QBC and GC\_QBC pins.
- It is advised to select the IO pins continuously without leaving any IO pairs in the middle of D-PHY interface. The following figure shows the recommendation message that appears in the GUI.

- D-PHY IP uses IO in Native mode. Using the left out IO's in the nibble is not recommended. If this is necessary, refer to "Mixing Native and Non-Native Mode I/O in a Nibble" section in *UltraScale Architecture SelectIO Resources User Guide* ([UG571](#)).
- HSSIO internally uses few IO under certain IO selection scenarios for strobe propagation and this can be avoided by selecting IO continuously. Pin(s) used for Strobe propagation will be DBC, QBC or GC\_QBC and it will restrict you to implement the multiple D-PHY interfaces.
- D-PHY with two different line rates can be implemented within IO bank and each D-PHY interface will use one PLL.
- All the lanes of a particular MIPI D-PHY instance need to be in the same HP IO bank, which the Pin Assignment tab of XGUI automatically controls for UltraScale+ devices.

- In case of multiple D-PHY instances sharing clocking resources, all such instances also need to be in the same HP IO bank.
- Any IO being placed along with D-PHY interface should have DCI IO standard because D-PHY IO uses MIPI\_DPHY\_DCI IO Standard.
- IO used for data lanes can be swapped in any order by keeping RX clock lane IO LOC unchanged.

The following table shows an example of a four 4-lane D-PHY interface that be implemented in a single HP IO bank.

**Table 37: 4x4-lane D-PHY Interface**

| Interface | Signal Name | Byte Group | Pin Type |
|-----------|-------------|------------|----------|
| -         | -           | T3U_12     | -        |
| -         | -           | T3U_11     | N        |
| -         | -           | T3U_10     | P        |
| if3       | data_rxn[3] | T3U_9      | N        |
| if3       | data_rxp[3] | T3U_8      | P        |
| if3       | data_rxn[2] | T3U_7      | N        |
| if3       | data_rxp[2] | T3U_6      | P        |
| if3       | data_rxn[1] | T3L_5      | N        |
| if3       | data_rxp[1] | T3L_4      | P        |
| if3       | data_rxn[0] | T3L_3      | N        |
| if3       | data_rxp[0] | T3L_2      | P        |
| if3       | clk_rxn     | T3L_1      | N        |
| if3       | clk_rxp     | T3L_0      | P        |
| -         | -           | T2U_12     | -        |
| -         | -           | T2U_11     | N        |
| -         | -           | T2U_10     | P        |
| if2       | data_rxn[3] | T2U_9      | N        |
| if2       | data_rxp[3] | T2U_8      | P        |
| if2       | data_rxn[2] | T2U_7      | N        |

## Strobe Propagation for D-PHY RX

Device architecture within BITSlice and BITSlice\_CONTROL allows the user to propagate the Strobe between byte groups by using additional IO pin(s) internally. Additional pin usage for Strobe propagation depends on the RX clock lane IO (Strobe) selection along with RX data lane IO selection.

**Note:** Strobe propagation is not applicable if DBC pin is selected as RX clock lane IO.

The following table provides the scenarios for additional IO realization by HSSIO IP wizard for Strobe propagation. This pin(s) are generated with `bg<>_pin<>_nc` name. N pins are not shown in the following table for simplicity.

Table 39: Strobe Propagation for D-PHY RX Interface

| Byte Group | T1L_0 as RX Clock Lane IO                                | T1U_6 as RX Clock Lane IO                                | T2L_0 as RX Clock Lane IO                 | T2U_6 as RX Clock Lane IO                 |
|------------|----------------------------------------------------------|----------------------------------------------------------|-------------------------------------------|-------------------------------------------|
| T3U_10     | Selecting this IO forces bg2_pin0_nc and bg3_pin0_nc use | Selecting this IO forces bg2_pin6_nc and bg3_pin6_nc use | Selecting this IO forces bg3_pin0_nc use  | Selecting this IO forces bg3_pin6_nc use  |
| T3U_8      | Selecting this IO forces bg2_pin0_nc and bg3_pin0_nc use | Selecting this IO forces bg2_pin6_nc and bg3_pin6_nc use | Selecting this IO forces bg3_pin0_nc use  | Selecting this IO forces bg3_pin6_nc use  |
| T3U_6      | Selecting this IO forces bg2_pin0_nc and bg3_pin0_nc use | bg3_pin6_nc are inferred by using this IO                | Selecting this IO forces bg3_pin0_nc use  | bg3_pin6_nc are inferred by using this IO |
| T3L_4      | Selecting this IO forces bg2_pin0_nc and bg3_pin0_nc use | Selecting this IO forces bg2_pin6_nc and bg3_pin6_nc use | Selecting this IO forces bg3_pin0_nc use  | Selecting this IO forces bg3_pin6_nc use  |
| T3L_2      | Selecting this IO forces bg2_pin0_nc and bg3_pin0_nc use | Selecting this IO forces bg2_pin6_nc and bg3_pin6_nc use | Selecting this IO forces bg3_pin0_nc use  | Selecting this IO forces bg3_pin6_nc use  |
| T3L_0      | bg3_pin0_nc are inferred by using this IO                | Selecting this IO forces bg2_pin6_nc and bg3_pin6_nc use | bg3_pin0_nc are inferred by using this IO | Selecting this IO forces bg3_pin6_nc use  |
| T2U_10     | Selecting this IO forces bg2_pin0_nc use                 | Selecting this IO forces bg2_pin6_nc use                 | Same Byte Group                           | Same Byte Group                           |

Table 39: Strobe Propagation for D-PHY RX Interface (cont'd)

| Byte Group | T1L_0 as RX Clock Lane IO                 | T1U_6 as RX Clock Lane IO                 | T2L_0 as RX Clock Lane IO                                | T2U_6 as RX Clock Lane IO                                |
|------------|-------------------------------------------|-------------------------------------------|----------------------------------------------------------|----------------------------------------------------------|
| T2U_8      | Selecting this IO forces bg2_pin0_nc use  | Selecting this IO forces bg2_pin6_nc use  | Same Byte Group                                          | Same Byte Group                                          |

| T1L_0      | RX Clock Lane IO                          | Same Byte Group                           | bg1_pin0_nc are inferred by using this IO                | Selecting this IO forces bg1_pin6_nc use                 |
| T0U_10     | Selecting this IO forces bg0_pin0_nc use  | Selecting this IO forces bg0_pin6_nc use  | Selecting this IO forces bg0_pin0_nc and bg1_pin0_nc use | Selecting this IO forces bg0_pin6_nc and bg1_pin6_nc use |
| T0U_8      | Selecting this IO forces bg0_pin0_nc use  | Selecting this IO forces bg0_pin6_nc use  | Selecting this IO forces bg0_pin0_nc and bg1_pin0_nc use | Selecting this IO forces bg0_pin6_nc and bg1_pin6_nc use |
| T0U_6      | Selecting this IO forces bg0_pin0_nc use  | bg0_pin6_nc are inferred by using this IO | Selecting this IO forces bg0_pin0_nc and bg1_pin0_nc use | bg0_pin6_nc are inferred by using this IO                |
| T0L_4      | Selecting this IO forces bg0_pin0_nc use  | Selecting this IO forces bg0_pin6_nc use  | Selecting this IO forces bg0_pin0_nc and bg1_pin0_nc use | Selecting this IO forces bg0_pin6_nc and bg1_pin6_nc use |
| T0L_2      | Selecting this IO forces bg0_pin0_nc use  | Selecting this IO forces bg0_pin6_nc use  | Selecting this IO forces bg0_pin0_nc and bg1_pin0_nc use | Selecting this IO forces bg0_pin6_nc and bg1_pin6_nc use |
| T0L_0      | bg0_pin0_nc are inferred by using this IO | Selecting this IO forces bg0_pin6_nc use  | bg0_pin0_nc are inferred by using this IO                | Selecting this IO forces bg0_pin6_nc and bg1_pin6_nc use |

## D-PHY TX Pin Rules

- Select the HP IO bank that has the VRP pin. DCI\_CASCADE is allowed from HP IO bank of the same IO column in case the VRP pin is grounded for the selected HP IO bank.
- Select the IO pins continuously without leaving any IO pairs in the middle of D-PHY interface.

- Because D-PHY IP uses IO in Native mode, left out IO cannot be used by any other design and is unusable.
- D-PHY with two different line rates can be implemented within an IO bank and each D-PHY interface uses one PLL.
- All the lanes of a particular MIPI D-PHY instance need to be in the same HP IO bank, which the Pin Assignment Tab of XGUI automatically controls for UltraScale+.
- In the case of multiple MIPI D-PHY instances sharing clock resources, all such instances need to be in the same HP IO bank.
- IO used for clock lane and data lane(s) can be swapped in any order for D-PHY TX IP.

---

## Pin Rules for 7 Series FPGAs

This section describes the pin rules for 7 series FPGAs:

- Non-continuous IO usage is allowed for D-PHY TX and RX interfaces but not recommended.
- Restrict the IO selection within the single IO bank.
- Select SRCC/MRCC pins for D-PHY RX clock lane.

## Finding Additional Documentation

### Technical Information Portal

The AMD Technical Information Portal is an online tool that provides robust search and navigation for documentation using your web browser. To access the Technical Information Portal, go to <https://docs.amd.com>.

### Documentation Navigator

Documentation Navigator (DocNav) is an installed tool that provides access to AMD Adaptive Computing documents, videos, and support resources, which you can filter and search to find information. To open DocNav:

- From the AMD Vivado™ IDE, select **Help** → **Documentation and Tutorials**.
- On Windows, click the **Start** button and select **Xilinx Design Tools** → **DocNav**.
- At the Linux command prompt, enter `docnav`.

**Note:** For more information on DocNav, refer to the *Documentation Navigator User Guide* ([UG968](#)).

### Design Hubs

AMD Design Hubs provide links to documentation organized by design tasks and other topics, which you can use to learn key concepts and address frequently asked questions. To access the Design Hubs:

- In DocNav, click the **Design Hubs View** tab.
- Go to the [Design Hubs](#) web page.

---

## Support Resources

For support resources such as Answers, Documentation, Downloads, and Forums, see [Support](#).

### **AUTOMOTIVE APPLICATIONS DISCLAIMER**

AUTOMOTIVE PRODUCTS (IDENTIFIED AS "XA" IN THE PART NUMBER) ARE NOT WARRANTED FOR USE IN THE DEPLOYMENT OF AIRBAGS OR FOR USE IN APPLICATIONS THAT AFFECT CONTROL OF A VEHICLE ("SAFETY APPLICATION") UNLESS THERE IS A SAFETY CONCEPT OR REDUNDANCY FEATURE CONSISTENT WITH THE ISO 26262 AUTOMOTIVE SAFETY STANDARD ("SAFETY DESIGN"). CUSTOMER SHALL, PRIOR TO USING OR DISTRIBUTING ANY SYSTEMS THAT INCORPORATE PRODUCTS, THOROUGHLY TEST SUCH SYSTEMS FOR SAFETY PURPOSES. USE OF PRODUCTS IN A SAFETY APPLICATION WITHOUT A SAFETY DESIGN IS FULLY AT THE RISK OF CUSTOMER, SUBJECT ONLY TO APPLICABLE LAWS AND REGULATIONS GOVERNING LIMITATIONS ON PRODUCT LIABILITY.
